In Figure 4, we show the $\log_2$ ratios of the χ^2 fits to the $\mathbf{A}_S$ matrix between BD-TF and BD. The heatmaps show the differences in the fits across different levels of noise and inclusion of prior information. In the figures, multiplicative noise increases to the right, from 0 to 48% of the peak signal; additive noise to the top, from 0 to 79% of peak signal; and the amount of prior information included (number of genes included from coregulation lists) increases as indicated by the percentages shown above each heatmap. Only the 36 simulations with the lowest noise levels are shown, as these cover levels of noise exceeding those in typical array experiments. Gray squares represent a neutral result (no improvement), while lighter squares represent improved fits with BD-TF and darker squares poorer fits. The advantage of using coregulation information increases as levels of prior information increase, as would be expected if the coregulation information is improving statistical inference by gaining power across genes.

Yeast cell cycle

In Figure 5 on the left, we present results of the application of BD-TF to the cell cycle data using ROC analysis based on known coregulation [13]. We compared the results using original BD (circles), BD-TF (squares), and shrinkage-based hierarchical clustering (triangles; performed previously [13]). BD-TF obtained an area under the curve of 0.82, compared with 0.83 for BD and 0.56 for hierarchical clustering. The lack of improvement from use of coregulation information reflected the lack of such data here, as we had TF data on only 67 of 788 genes, which was not adequate to improve inference over BD. However, we include the results to show the value in BD and BD-TF

that arises solely from the proper assignment of genes to multiple groups.

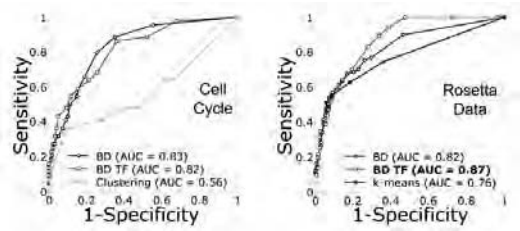

Figure 5 – ROC Curves for Cell Cycle and Rosetta Data

Rosetta compendium

The analysis of data from the Rosetta compendium data set using BD-TF (squares) was compared to K-means clustering (triangles) and the original BD analysis (circles) of the same data (Figure 5 right). Here, both the coregulation information and the "gold" standard gene lists were the same, so that the results demonstrated that the algorithm correctly used information about TF regulation and that such coregulation was reflected in the data. All techniques performed equally well at high specificity, however as sensitivity increased, BD-TF was superior due to a reduction of false positives with the inclusion of prior information on TF regulation.

Conclusion

This work demonstrates 1) the value of inclusion of prior knowledge on transcriptional regulation in the analysis of microarray data, and 2) the present limits of that knowledge. While the simulations showed a clear advantage in using this knowledge, especially at typical noise levels, the analysis of cell cycle data indicated that more prior information would be helpful. Nevertheless, the superiority of the BD-TF approach over clustering for microarray analysis is clear. Our knowledge of transcriptional regulation is rapidly increasing, and we expect improved statistical power with BD-TF over the next few years. This power will be critical to improved inference of biological process activity, especially with heterogeneous and limited samples typical in clinical settings. These samples introduce noise to an analysis focused on understanding biological response, such as in therapeutic interventions, and techniques to gain statistical power through use of existing biological knowledge will be critical to make progress.

Abstract

Microarray data sets for cancer tumor tissue generally have very few samples, each sample having thousands of probes (i.e., continuous variables). The sparsity of samples makes it difficult for machine learning techniques to discover probes relevant to the classification of tumor tissue. By combining data from different platforms (i.e., data sources), data sparsity is reduced, but this typically requires normalizing data from the different platforms, which can be non-trivial. This paper proposes a variant on the idea of ensemble learners to circumvent the need for normalization. To facilitate comprehension we build ensembles of very simple classifiers known as decision stumps – decision trees of one test each. The Ensemble Stump Classifier (ESC) identifies an mRNA signature having three probes and high accuracy for distinguishing between adenocarcinoma and squamous cell carcinoma of the lung across four data sets. In terms of accuracy, ESC outperforms a decision tree classifier on all four data sets, outperforms ensemble decision trees on three data sets, and simple stump classifiers on two data sets.

Keywords:

microarray, decision trees, ensembles, stumps

Introduction

Methods for finding robust mRNA signatures of cancer that remain consistent across experiments and microarray platforms (i.e., oligonucleotide and cDNA) have remained elusive in the bioinformatics literature. From a machine learning perspective this is expected, since many microarray data sets have a scarcity of sample (e.g., a few hundred); moreover, each sample has thousands of probes (i.e., continuous variables) resulting in a very pronounced curse of dimensionality. With thousands of variables from which to choose, the constructed classifier can overfit the specific data and cannot generalize to other data sets. It poses a challenge when applying machine learning techniques to discover a set of relevant probes that constitute a robust mRNA signature for the cancer. There are a number of papers describing the pitfalls of overfitting expression data and the failure of some classification models to do better than chance [1,2,3].

By combining data from different platforms, problems of data sparsity and overfitting can be mitigated. The microarray data sets available in repositories are growing at a rapid rate. The creation of data sharing initiatives such as oncomine.org and the Cancer Biomedical Informatics Grid (caBIG™) enable the combination of multiple data sets to find better classifiers.

However, combining data across platforms is challenging. First of all, there are multiple microarray platforms and these can differ in the types of probes arrayed (i.e. variables measured) for the specimens. A method for mapping the probes across platforms is first required to relate the results. The different means of getting expression levels from the platforms need to be consistently compared, which often requires normalizing the expression levels between platforms.

A methodology that supports the generation of classifiers that find easily interpretable, robust mRNA signatures of cancer that *generalize across experiments and platforms* is needed. By robust mRNA signatures what is meant is a set of probes that are consistently associates with a cancer type. This paper describes a novel method for combining data sets to discover classifiers that use robust mRNA signatures which generalize across experiments and platforms. This is done by using a classifier to focus on a limited number of predictive probes in the data that persist across data sets. *The result of our approach is a distinct classifier for each data set under investigation, but importantly the construction of each such classifier is informed by all the available data.*

Empirical results by Holte [4] showed that simple, single test classifier trees, referred to as *Stumps*, can be surprisingly close in accuracy to more complex decision tree classifiers[5] in many of the domains tested. Results on data sets used in machine learning have shown that combining multiple classifiers boosts classification accuracy by creating variance among the constituent classifiers. Our approach, Ensemble Stump Classifier (ESC), is a kind of subspace sampling. It combines different probes that have slightly dissimilar classification of the sample using a majority vote to boost accuracy due to the variance in the sample they accurately classify. Using Stump classifiers as the "base" classifier of the ensemble supports the creation of simple ensemble classifiers.

Materials and methods

Four classifier-methods -- decision trees (C5.0), ensemble decision trees, Stump rule and ESC -- are applied to the data sets. Ten-fold cross validation is used to derive the accuracy measure for the data sets. Each data set is divided into 10 mutually-exclusive folds, consisting of 10% of the data. One of the 10-folds is held out as a testing set and the remaining 90% is used as the training set. Then a different fold is selected as the testing set and the remaining 90% serves as the training set. The average testing accuracy is calculated across all 10-folds.

C5.0, ensemble C5.0 and stumps

C5.0 is a commercial implementation of Quinlan's decision tree approach [5]. The ensemble decision tree classifier is computed using C5.0's implementation of the boosting approach of Freund and Schapire [6]. Stumps are single variable-test decision trees. Each Stump is made up of one probe at the root and has the best threshold for the training set that separates the two classes. Stumps are obtained by running C5.0 rules on a single data set with pruning set to a 1% confidence level with only single variable rules allowed.

Ensemble stump classifier (ESC)

The ESC is a new classifier approach that bypasses the need to normalize across multiple data sets. The base classifier for the ensemble is the Stump classifier. *The outcome of our method is a separate classifier for each data set, but notably each classifier is instructed by all the available data.*

Basic representations

ESC's form of ensemble learning is different than boosting. The idea that learning is occurring over multiple data sets is key. To illustrate, consider three artificially constructed objects, one from each of three data sets (see Table 1a).

Probes P_{1j} (i.e., a *matching probe set*) represent "synonymous" probes across the three data sets. The three probes -- P_{11}, P_{12}, and P_{13} -- can be thought of as the same probe with different scales and labels. The probe P_{11} has an expression value for the probe in match Probe Set 1 and Data Set 1.

The ESC algorithm repeatedly finds the "probe" (though with different labels and scales) that is "collectively" best over all data sets. This step leads to one decision stump per data set, each of which uses the same decision variable/probe. For example, if probe P_1 were found to be "collectively best" over three data sets, then the three decision stumps for each data set would have the form expressed in Table 1b.

The threshold for match Probe Set 1 in Data Set 1 is equal to 0.7 in Table 1b. Given an expression value for probe P_{11} equal to or below 0.7 the Stump rule predicts Class 1, otherwise Class 2. For Probe Set 1 and Data Set 2 the threshold is different than Data Set 1 (compare threshold 0.7 for P_{11} and threshold 10 for P_{12}). Even though the probes are the same, the thresholds can be different between data sets. This occurs because the data sets are not normalized to each other. The threshold is only consistent within a data set.

Building an ESC

The following are the steps to generate a full ensemble stump classifier (as in Table 1b):

1. Determine which probes match each other and construct rows based on the matching (i.e., "synonymous") probes across the data sets. This was briefly described in the basic representations section, and is described in more detail in the match probes section.
2. Partition each of the three data sets into folds so that there are training and testing sets. In our experimental design we use 10-fold cross validation.
3. Learn the stump rules, one for each training set and matching probe set, from training folds. This was illustrated in the basic representations section (e.g., each P_{ij} in Table 1b), and follows the same process given for stump rules.
4. Reorder the stumps across the data sets based on the probes that are "collectively" best overall.
5. Determine the best number of probes to be in the ESC based on training accuracy.

Step 4 is implemented by ordering the stump rules generated in Step 3 according to the weighted average training accuracy across the data sets. The average accuracy is weighted by the size of the data sets. Step 5 is implemented by incrementally adding stump classifiers in order of quality (accuracy) until one fails to improve the accuracy of the ESC.

Classification with an ESC

Table 1a illustrates the data structures for three data sets with probes having expression values and each instance having a true class assigned. The true classes are assigned to the instance through an expert classifying the instance. For cancer tissues the expert is often a pathologist. Table 1b illustrates the data structure for an ESC consisting of three probes over three data sets. The thresholds and predictive classes are shown for the probes for each data set.

Table 1c is the substitution of the expression values for the probes from Table 1a into the data structures for ESC in Table 1b. The predicted classes are present for each probe. The cells that are grey in Table 1c are incorrect class assignments given the expression values and the thresholds. The bolded classes are correct assignments. For example in Table 1c, P_{11} is incorrectly assigned while P_{12} and P_{13} are correctly assigned. Two out of three correct gives an accuracy of 66.7%.

The ESC majority vote classifier is obtained by going down a column and choosing the majority class predicted by the rules. An odd number of probes are used in the ensemble for simplicity and to ensure there is always a winner. For example in Data Set 1 the majority class is 1 because P_{21} and P_{31} are both correctly assigned to Class 1. For Data Set 2 the Majority Class is 2 because P_{12} and P_{22} are both correctly assigned to Class 2. Going across the majority vote row gives three out of three correct for an accuracy of 100%. Table 2 is the accuracy of the probe sets across the data sets and the ESC accuracy. Because we have not normalized the classifiers in ESC, the column or data set against which the test instance is compared must be known; we will address this limitation in the discussion.

Table 1 - Obtaining accuracy given an instance and an example ESC.

(a) Test instance with expression values and class.			
	Data 1	**Data 2**	**Data 3**
Test Instance with expression values for probes	(P_{11}=0.8, P_{21}= 0.85, P_{31}=1.5)	(P_{12}=12, P_{22}=14, P_{32}=15.5)	(P_{13}=0.02, P_{23}=0.35, P_{33}= 0.55)
True Class	Class 1	Class 2	Class 1
(b) Example ESCs for the three probe sets and data sets:			
Match Probe	**Data Set 1**	**Data Set 2**	**Data Set 3**
P_{1j}	P_{11} <= 0.7 ->Class 1 P_{11} > 0.7 -> Class 2	P_{12} <= 10 ->Class 1 P_{12} > 10 -> Class 2	P_{13} <= 0.1 ->Class 1 P_{13}> 0.1 -> Class 2
P_{2j}	P_{21} <= 0.9 ->Class 1 P_{21} > 0.9 -> Class 2	P_{22} <= 12 ->Class 1 P_{22} > 12 -> Class 2	P_{23} <= 0.3 ->Class 1 P_{23} > 0.3 -> Class 2
P_{3j}	P_{31} <= 1.2 ->Class 2 P_{31} > 1.2 -> Class 1	P_{32} <= 15 ->Class 2 P_{32} > 15 -> Class 1	P_{33} <= 0.5 ->Class 2 P_{33} > 0.5 -> Class 1
ESC	Majority class predicted by P_{11}, P_{21} & P_{31} Stump rules	Majority class predicted by P_{12}, P_{22} & P_{32} Stump rules	Majority class predicted by P_{13}, P_{23} & P_{33} Stump rules
(c) Class predictions given expression values from 1(a) and classifiers from 1(b). Bold is correct and grey is incorrect as compared to true class in 1(a).			
Match Probe	**Data Set 1**	**Data Set 2**	**Data Set 3**
P_{1j}	0.8 > 0.7 -> Class 2	12 > 10 -> **Class 2**	0.02 <= 0.1 ->**Class 1**
P_{2j}	0.85 <= 0.9 ->**Class 1**	14 > 12 -> **Class 2**	0.35 > 0.3 -> Class 2
P_{3j}	1.5 > 1.2 -> **Class 1**	15.5 > 15 -> Class 1	0.55 > 0.5 -> **Class 1**
ESC	Majority class predicted by P_{11}, P_{21} & P_{31} Stump rules -> **Class 1**	Majority class predicted by P_{12}, P_{22} & P_{32} Stump rules -> **Class 2**	Majority class predicted by P_{13}, P_{23} & P_{33} Stump rules -> **Class 1**

Table 2 - Accuracy across the three data sets of the match probe sets and the ESC.

Match Probe	P_{1j}	P_{2j}	P_{3j}	ESC
Accuracy	66.7%	66.7%	66.7%	100%

Gene expression data

There are four data sets. Collectively, these data sets are made up of two affymetrix arrays and two cDNA microarrays data sets. There are two types of tumor tissue: adenocarcinoma and squamous cell carcinoma of the lung. The Su et al. [7] data set consists of 28 samples with 14 adenocarcinomas and 14 squamous cell carcinomas of the lung with 12,533 affymetrix probes (i.e., continuous variables). The Bhattacharjee et al. [8] data set consists of 160 samples with 139 adenocarcinomas and 21 squamous cell carcinomas of the lung with 12,600 affymetrix probes. The Yamagata et al. [9] data set consists of 20 samples with 9 adenocarcinomas and 11 squamous cell carcinomas of the lung with 4417 cDNA probes. The Garber et al. [10] data set consists of 52 samples with 39 adenocarcinomas and 13 squamous cell carcinomas of the lung with 24,192 cDNA probes.

Matched probes

Before obtaining an ESC we must identify matching probes across data sets. While the other classifier methods that we have described will be applied to each of the four data sets independently, an ESC will be learned from the "combined" data set that we are about to describe.

A probe corresponds to part of a gene. Thus, different probes can be associated with the same gene. The same gene may be referenced by different probes in different data sets obtained on different platforms. In order to use an ensemble method that generalizes across different data sets, the Affymetrix and cDNAs probes must be mapped to each other. For this paper all probes are matched via Affymetrix U95A probe names. For the ensemble method the probe sets are matched as follows. Bhattacharjee et al. and Su et al. are joined via their almost identical chips, which are

U95Av2 and U95A Affymetrix chips respectively. Thus they have total overlap of 12533 unique probes. Garber et al. and Yamagata et al. also have similar cDNA probes with a unique overlapping set of 2106 accession id probes.

Consequently, we have two pairs of similar platforms. It is trivial to map probes across platforms within each pair. To map across the pairs (i.e., across all four platforms) an online resource called ProbeMatchDB [11] is used to map these 2106 accession ids onto the U95A Affymetrix ids in a many-to-many mapping. The many-to-many mapping occurs because some of the 2106 cDNA probes have multiple U95A Af-fymetrix ids associated with them. All possible combinations of probes from the four data sets with matching U95A Af-fymetrix ids are used to construct the probe sets. This match-ing process results in the creation of 4491 probe sets. The probe sets are made up of four probes with one from each data set. A probe set can be thought of as a set of references for the same gene. In the discussion that follows we use "probe set" and "gene" synonymously.

Results

The four classification methods described above (i.e., ESC, Stump Rule, C5.0 and Ensemble C5.0) are compared using 10-fold cross validation testing accuracy, standard error and the average number of variables (Avg Var) for each classifier (See Table 3). Each C5.0 tree, Ensemble C5.0 forest and Stump Rule has been built in a way that is informed by a single data set. Thus, we will speak of classifications made by these approaches as using probes.

The ESC method uses the same 4,491 match probe sets or genes for each data set. As we have noted, the construction of ESCs are informed by multiple data sets, but to classify a datum with an ESC we must know the data set (e.g., what column in Table 1) that test instance is drawn.

The ESC does better than C5.0 on all four data sets, better than ensemble C5.0 on three out of four sets and better on two out of four for Stump Rule. Note that the ESC uses probes that are robust across the four data sets rather than using the best probes for each given data set. The Stump Rule, C5.0 and ensemble C5.0 are all using the best probes within a given data set, which gives them an advantage for computing accuracy, although not on generalization to other data sets.

A measure of the complexity of the classifiers is given in the mean number of variables across folds for a classifier. The ESC converges to a classifier of three variables (genes: BPAG1, KRT5 and ABCC5) for nine out of the 10-folds. As explained earlier, this number of genes does not result from a user-defined threshold, but to add more stumps (i.e., genes) to the ensemble would reduce training set accuracy. In the one remaining fold ESC converges to BPAG1, KRT5 and SIAT7B which results in a total of four variables used by the classifier. The thresholds in the rules are stable within each data set and hence there is consensus among the stumps in the cross-validation step Ensemble C5.0, C5.0 and Stump use varying number of probes for each data set, but they do not find probes that generalize across all four data sets.

Discussion

ESCs are not limited to genomic data per se, and we are interested in their characteristics from a machine learning standpoint. Ensembles boost accuracy by insuring variability in classification behavior among the base classifiers. In bagging [12] this variance stems from bootstrap sampling and the instability of the classifiers that are constructed with these differing sample. In random subspace selection the requisite variance comes from selection of differing variables [13] on which to form the classifier. To some extent such designs might be motivated by a desire to use off-the-shelf, greedy decision tree induction, which is a standard base classifier of ensemble approaches. Another way that variance could be achieved would be to modify classifier systems to directly return a set of sufficiently good and sufficiently different classifiers. In fact, this is our approach, though our base classifiers are stumps – we incrementally add "best" stumps (as assessed across multiple data sets) until performance drops.

The limitation of knowing what column in ESC to apply to a particular data set is moot within a lab or facility since they will always compare on the data they collect. The benefit comes from being informed by data collected at other labs and facilities. In practice it can be used to identify signature genes that when combined enable the construction of high accuracy classifiers, even in hold-out data sets.

Table 3 - Adenocarcinoma vs. Squamous Cell Carcinoma for 10-fold cross validation test accuracy for ESC, Stump classifiers, C5.0 decision tree, Ensemble C5.0 and SVMs with standard error (SE) and average number of variables across folds (Avg Var) in the classifier.

Data Set	ESC			Stump Rule			C5.0			Ensemble C5.0		
	Avg Acc %	SE	Avg Var	Avg Acc %	SE	Avg Var	Avg Acc %	SE	Avg Var	Avg Acc %	SE	Avg Var
Bhattacharjee	95.6	1.3	3	96.9	1.0	1	93.7	1.6	3	94.4	1.7	1.3
Su	93.3	4.4	3	83.3	7.5	1	91.7	5.7	1	90.0	7.1	1
Garber	91.8	3.4	3	92.7	3.1	1	87.0	4.8	1.4	88.3	4.4	1.2
Yamagata	95.0	5.0	3	40.0	10.0	1	80.0	11.1	1	90.0	6.7	1

Whenever ensembles succeed in boosting accuracy it can be argued that the base classifiers, by definition, must be overfitting or underfitting the data. The ensemble then results in a classifier that moves towards a "best" fit to the data. In the case of an ensemble of decision trees that boost accuracy, the move is probably from overfit to better fit. Overfitting may account for cases where C5.0 underperformed Stump Rule on

some data sets. In the case of ESCs the move is probably from underfit to better fit. ESCs are not only very simple, are formed from stumps that generalize well across data sets, and as a result may underfit any given data set.

One reason stumps that generalize well across data sets are desirable with microarray data is that artifacts can be introduced into the data by the lab that collects the data. Thus, the very best stump for a particular data set may exploit an environmental peculiarity of the lab that is collecting the data. When dealing in thousands of probes, any small laboratory bias may systematically influence the value of one or more probes [14]. Problems with data or facility bias are found in other contexts. For example, Evans and Fisher [15] found that a feature (i.e., printing press) that was highly predictive of a printing defect in a particular printing plant provided no insights to why similar problems occurred at other plants.

ESC builds classifiers that generalize across data sets (labs, facilities), and informs data collectors about probes that generalize beyond their data collection processes. When ESCs learned across data sets are contrasted with the best classifiers within a data set, our methodology can also point out lab biases that should be remedied.

ESCs were motivated initially by the desire to combine evidence from multiple sources of gene expression data, thereby mitigating the curse of dimensionality. We are interested then in what ESCs can tell in a biological domain. Notably, the ensemble method identifies the genes KRT5, BPAG1 and ABCC5 as informative across the four data sets that we examined. Importantly, the ESC method gives convergent support for the relevance of these probe sets relative to the findings in the original studies. Using hierarchical clustering Bhattacharjee et al. [8] found KRT5 and BPAG1 to be highly expressed in squamous cell carcinoma. Using hierarchical clustering Yamagata et al. [9] confirmed in their data that KRT5 and BPAG1 are highly expressed in squamous cell carcinoma. Using hierarchical clustering Garber et al. [10] also identified KRT5 and BPAG1 as highly expressed in squamous cell carcinoma. Using a SVM ranking method Su e al. [12] did not identify high expression of KRT5 or BPAG1 as predictive of squamous cell carcinoma. However, they did identify ABCC5 as predictive of squamous cell carcinoma. The convergent findings of these alternative methods provide additional support of the utility of the ESC method.

Conclusion

The ESC method does well with only three variables. These results suggest the existence of compact sets of genes with single thresholds, which can be measured using multiple modalities that consistently and accurately predict diagnosis. The building of data repositories and data exchange standards such as oncomine.com and the caBIG™ can assist in the discovering other robust mRNA signatures of cancer using ESC. The ESC finds in a greedy fashion the best available matched probes that can be used in an mRNA signature that generalizes across data sets.

Abstract

Entrez Gene (EG), Online Mendelian Inheritance in Man (OMIM) and the Gene Ontology (GO) are three complementary knowledge resources that can be used to correlate genomic data with disease information. However, bridging between genotype and phenotype through these resources currently requires manual effort or the development of customized software. In this paper, we argue that integrating EG and GO provides a robust and flexible solution to this problem. We demonstrate how the Resource Description Framework (RDF) developed for the Semantic Web can be used to represent and integrate these resources and enable seamless access to them as a unified resource. We illustrate the effectiveness of our approach by answering a real-world biomedical query linking a specific molecular function, glycosyltransferase, to the disorder congenital muscular dystrophy.

Keywords:

knowledge integration, Semantic Web, RDF, Entrez Gene, Gene Ontology

Introduction

A common scenario in biomedical research involves the correlation of genomic data with disease information, in other words, associating genotype and phenotype information. In the particular scenario illustrated in this paper, a researcher is interested in glycosylation and its implications for one disorder: congenital muscular dystrophy. The biological process of glycosylation results in the post-translational addition of glycosyl groups (saccharides) to proteins (and lipids). Various enzymes, namely glycosyltransferases, catalyze glycosylation reactions.

From the functional annotation of gene products with terms from the Gene Ontology (GO), a researcher can identify the genes having the molecular function of catalyzing the transfer of specific glycosyl groups (e.g., *hexosyltransferase*, for hexosyl groups). Known associations between these genes and diseases can then be mined from resources such as NCBI's Entrez Gene (EG), where phenotypic information is recorded as pointers to the Online Mendelian Inheritance in Man (OMIM) knowledge base [3]. (See the Materials section for a presentation of GO and EG.)

In order to validate the hypothesis of possible association between the molecular function *glycosyltransferase* and the disease *congenital muscular dystrophy*, a researcher could simply search EG for the term *glycosyltransferase*, and all records containing the string "glycosyltransferase" in GO annotations would be returned. This approach, however, is suboptimal for at least two reasons. First, the term *glycosyltransferase* might appear as a substring in other GO terms (e.g., in *UDP-glycosyltransferase*), possibly leading to false positives. Conversely, not all GO terms related to *glycosyltransferase* actually contain the string "glycosyltransferase" (e.g., *acetylglucosaminyltransferase*, a kind of *glycosyltransferase*), possibly leading to false negatives.

To avoid false positives and false negatives, a careful researcher would likely start exploring the Gene Ontology database to create a list of *glycosyltransferase*-related terms by selecting the term *glycosyltransferase* itself (GO:0016757) and all its descendants, including specialized types of *glycosyltransferase*, such as *acetylglucosaminyltransferase*. This researcher would then look for the genes annotated with any of the *glycosyltransferase*-related terms. Resources such as the web browser AmiGO [1] support such searches and can retrieve the genes associated with any descendant of a given GO term. Finally, each of the genes found associated with any of the *glycosyltransferase*-related terms must be searched individually in EG, looking for mentions of the disease *congenital muscular dystrophy* (as an OMIM phenotype) in the corresponding records.

The procedure described above is evidently inefficient, time consuming and error prone as several web interfaces need to be utilized (AmiGO and Entrez), and as the results of the search in one resource need to be copied and pasted as search terms in the other. The main reason for such inefficiency is that high quality resources such as GO and EG have been designed primarily for consultation by humans, not for automated processing by agents or integration in applications. Moreover, these resources have been developed by different groups, independently of each other and are therefore not interoperable. No system currently supports complex queries such as: *Find all the genes annotated with glycosyltransferase-related terms in GO and associated with the disease congenital muscular*

dystrophy in OMIM. Typically, querying across the different knowledge sources is accomplished manually through meticulous work or requires the development of complex and customized software applications.

In this paper, we propose an integrative approach to querying across knowledge sources. More specifically, we have applied Resource Description Framework (RDF) [4] standard developed by the World Wide Web Consortium (W3C) to integrate knowledge from GO and EG, and used this integrated resource to answer complex queries. We use the scenario presented earlier to illustrate the advantages of this approach. This work is a pilot contribution to the *Biomedical Knowledge Repository* under development at the U.S National Library of Medicine (NLM) as part of the *Advanced Library Services* project [8]. This repository integrates knowledge not only from structured resources (database and knowledge bases), but also from the biomedical literature (e.g., MEDLINE), in order to support applications, including knowledge discovery.

Background

Information integration is one of the most challenging areas of research in Computer Science [11]. The use of heterogeneous schemas for data storage, that are designed primarily to ensure optimization of storage space, makes it extremely difficult for users to query data sources in an integrated manner. (The interested reader is referred to [12] for a survey of approaches to information integration.) The Semantic Web provides a common framework that enables the integration, sharing and reuse of data from multiple sources. The use of a representation formalism based on a formal language enables software applications to 'understand' and reason over information. Recent research in Semantic Web technologies has delivered promising results to enable information integration across heterogeneous knowledge sources.

The Resource Description Framework (RDF) is a W3C-recommended framework for representing data in a common format that captures the logical structure of the data. This is in contrast to pure storage aspects addressed by traditional relational database schema. The RDF representational model uses a single schema in contrast to multiple heterogeneous schemas or Data Type Definitions (DTD) used to represent data in XML by different sources. Hence in conjunction with a single Uniform Resource Identifier (URI), all data represented in RDF form a single knowledge repository that may be queried as one knowledge resource. An RDF repository consists of a set of assertions or triples. Each triple is constituted of three entities namely, the *subject* – the triple pertains to this entity, the *object* – the entity that states something about the object and the *predicate* – the relationship between the *subject* and the *object*. For example, as shown in Figure 1, assertions such as *acetylglucosaminyltransferase* (GO:0008375) is a kind of *hexosyltransferase* (GO:0016758) and the gene *LARGE* (EG:9215) has molecular function *acetylglucosaminyltransferase* (GO:0008375) can be represented as RDF triples.

The RDF triples often share nodes, thus forming a graph. For example, the two triples shown in Figure 2 share the node *acetylglucosaminyltransferase* (GO:0008375). The resulting graph is shown in Figure 2. The graph structure created by RDF is key to information integration in the Semantic Web.

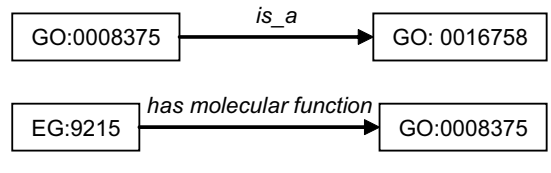

Figure 1 - Example of RDF triples

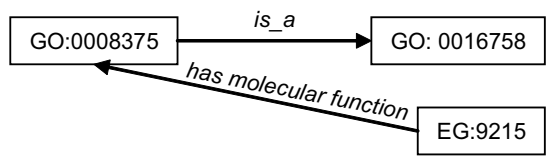

Fiigure 2 - Example of RDF graph

Materials

The **Gene Ontology** (GO) seeks to provide a consistent description of gene products [13]. GO consists of three controlled vocabularies for biological processes (9,234 terms), molecular functions (7,456 terms) and cellular components (1,804 terms). The GO monthly releases are made available on the GO website in various formats, including RDF. The version of GO used in this study is dated of September 2006.

The **Entrez Gene** (EG) database records gene-related information from sequenced genomes and of model organisms that are focus of active research [9], totaling about two million genes. EG contains gene information about genomic maps, sequences, homology, and protein expression among others [9]. In contrast to GO, EG is not available in RDF, but in XML (converted from ASN1 by the program *gene2xml* provided by NCBI), and can be downloaded from the NCBI website. The version of EG used in this study is dated of July 2006.

Methods

Our integration method can be summarized as follows and is illustrated in Figure 3. First, we extract manageable subsets from the two resources to be integrated. We then have to convert the EG subset from XML to RDF. Finally, we load both RDF resources in a common store, apply inference rules, and issue queries against it.

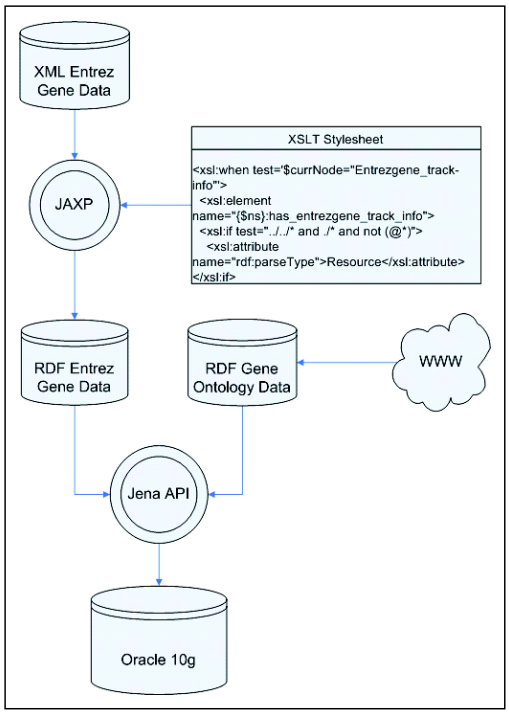

Figure 3 - Overview of the integration method

Creating subsets

The entire Entrez Gene data file (in XML format) is very large (50 GB) and unnecessarily difficult to manipulate. In order to obtain a manageable subset from EG, we restricted the gene records to two species: *Homo sapiens* (human) and *Mus musculus* (mouse). The resulting EG subset contains a total of 99,861 complete gene records (excluding obsolete records).

Converting XML format Entrez Gene data to RDF

A key element of our integration approach is the conversion of Entrez Gene from XML to RDF. There are many issues involved in the conversion of XML data into RDF format, including modeling the original semantics of the data, filtering redundant XML element tags, linking data entities using meaningful named relationships and identifying entities consistently within and across resources. Unlike traditional XML to XML conversion, XML to RDF conversion should exploit the advantages of the RDF model in representing the logical structure of the information.

We chose not to convert the element tags of the native EG XML representation mechanically into the *predicates* of the RDF triples. Instead, we manually converted the XML element tags into meaningful and standardized relationship names that convey explicitly the semantics of the connection between the *subject* and the *object*. For example, the element *<Org-ref_taxname>* was mapped to the more meaningful relationship named *has_source_organism_taxonomic_name*.

We selected the eXtensible Stylesheet Language Transformation (XSLT) [6] for converting the EG XML information into RDF, because this approach allows for a clean separation between the application (using Java API for XML Processing (JAXP)) and the conversion logic (using XSLT stylesheet). Once the stylesheet is created, it can serve as an auxiliary file for existing programs realizing the XML to RDF conversion. In other words, the major interest of this approach is that no specific code is required for the conversion, because the transformation logic resides entirely in the stylesheet.

Loading the two resources into a single data store

Some of the requirements for our RDF store include native support for the RDF graph data model, support for persistence and indexing of the RDF triples, support for extensive collections of triples, and availability of a query language for the RDF graph. After surveying available RDF storage solutions, we decided to use Oracle Spatial 10g [7] as the RDF storage system.

The RDF file resulting from the XSLT conversion of the original XML file for EG and the downloaded RDF version of GO are both loaded into a single RDF store. More precisely, the RDF resources are first converted to the NTriple format using the Jena API [10] and loaded into the RDF database using a utility program provided by Oracle.

Applying inference rules

Unlike the Web Ontology language OWL, RDF provides no direct support for inference. However, inference rules can be implemented in the RDF store to make explicit the semantics of some predicates. For example, the relationships *is_a* and *part_of* used in GO are partial order relations, thus being reflexive, antisymmetric and transitive. The inference rules we created for implementing the transitivity and combination of these two relationships are shown in Table 1. The inference rules are stored in a rule base created in Oracle 10g.

Table 1 - Inference rules for is_a and part_of in GO

Relation	is_a	part_of
is_a	IF <**x** *is_a* **y**> & <**y** *is_a* **z**> THEN <**x** *is_a* **z**>	IF <**x** *is_a* **y**> & <**y** *part_of* **z**> THEN <**x** *part_of* **z**>
part_of	IF <**x** *part_of* **y**> & <**y** *is_a* **z**> THEN <**x** *part_of* **z**>	IF <**x** *part_of* **y**> & <**y** *part_of* **z**> THEN <**x** *part_of* **z**>

Querying the RDF Graph with SPARQL

SPARQL [5] is a query language for RDF graphs, equivalent to SQL, the Structured Query Language, for relational databases. Unlike SQL, SPARQL does not require users to be familiar with the data model (e.g., tables, foreign keys), but simply to indicate how entities of interest relate to each other. For example, the structure of the query: *Find all the genes annotated with the GO molecular function glycosyl-*

*transferase (*GO:0016757) *or any of its descendants and associated with any form of congenital muscular dystrophy* is represented in Figure 4.

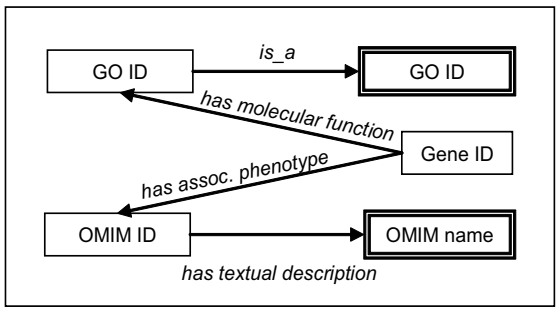

Figure 4 - RDF graph corresponding to the query above

```
SELECT distinct t,g,d
FROM TABLE(SDO_RDF_MATCH(
'(?t is_a GO:0016757)
 (?g has molecular function ?t)
 (?g has_associated_phenotype ?b2)
 (?b2 has_textual_description ?d)',
SDO_RDF_Models('entrez_gene'),
SDO_RDF_Rulebases('entrez_gene_rb'),
SDO_RDF_Aliases(SDO_RDF_Alias('','')), null) )
where (
    REGEXP_LIKE(LOWER(d), '((.)*(congenital)(.)*)')
AND REGEXP_LIKE(LOWER(d), '((.)*(muscular)(.)*)')
AND REGEXP_LIKE(LOWER(d), '((.)*(dystrophy)(.)*)'));
```

Figure 5 - Example of SPARQL query (simplified)

The query can be understood as finding a path in the RDF graph using a predetermined set of semantic relationships and would be formulated as follows. Because of the inference rules implementing the transitivity and reflexivity of the *is_a* relationship, the condition on the GO annotation "*glycosyltransferase (*GO:0016757) *or any of its descendants*" is easily expressed by '`?t is_a GO:0016757`'. The link between genes and GO terms is expressed by '`?g has_molecular_function ?t`'. Similarly, the link between genes and OMIM diseases is expressed by '`?g has_associated_phenotype ?b2`' (OMIM ID) and '`?b2 has_textual_description ?d`' (disease name). Finally, direct constraints are put on the GO term on the one hand ('`?t is_a GO:0016757`', to select *glycosyltransferase* (GO:0016757)) and on disease names on the other (where a regular expression is used to select disease names containing the strings "congenital", "muscular" and "dystrophy"). The actual (but simplified) SPARQL query is shown in Figure 5.

Results

One integrated RDF repository for Entrez Gene and GO

The subset of Entrez Gene restricted to *Homo sapiens* (human) and *Mus musculus* (mouse) as biological sources comprises 99,861 gene records. Once converted to RDF, it consists of 772,530 triples. The RDF version of GO contains 293,798 triples. Overall, there are over one million triples in the store created for this experiment, which is relatively small in comparison to the 411 million triples resulting from the conversion of the entire EG to RDF [2].

Biological query result: extended example

The SPARQL query presented above returned one result, corresponding to one path in the graph between the GO term *glycosyltransferase (*GO:0016757) and OMIM disease names containing (variants of) the string "*congenital muscular dystrophy*".

This path involved the human gene *LARGE like-glycosyltransferase* (EG:9215), annotated with the GO term *acetylglucosaminyltransferase* (GO:0008375), a descendant of *glycosyltransferase (*GO:0016757). Also involved in this path is the OMIM disease identified by MIM:608840. The name (textual description) of this disease is *Muscular dystrophy, congenital, type 1D* and contains the required substrings "congenital", "muscular" and "dystrophy". The instantiated RDF graph with path between *glycosyltransferase* (GO:0016757) and *Muscular dystrophy, congenital, type 1D* is shown in Figure 6.

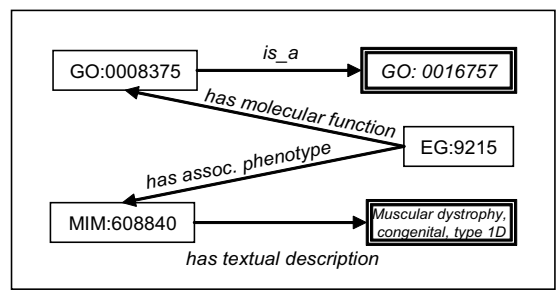

Figure 6 - Instantiated RDF graph

This simple SPARQL query provides an easy way of testing the biological hypothesis under investigation, i.e., the existence of a possible link between glycosylation and *congenital muscular dystrophy*. On manual inspection of the Entrez Gene record, we also note that the given gene may be involved in the development and progression of meningioma through modification of ganglioside composition and other glycosylated molecules in tumor cells.

Discussion

Significance

In this study, we demonstrated the feasibility of integrating two biomedical knowledge resources through RDF. We also provided anecdotal evidence for the benefits of such integration by showing how *glycosyltransferase* can be linked to *congenital muscular dystrophy*. The integrated resource is greater than the sum of its parts as it supports complex queries that could typically not be handled otherwise without tedious manual intervention or customized software applications.

Integrated resources based on a graph model are particularly important in an exploratory context where researchers need to "connect the dots" in order to validate an hypothesis. This approach also facilitates intuitive

hypothesis formulation and refinement. For example, after verifying that glycosyltransferase is linked to congenital muscular dystrophy, our researchers may narrow the focus of their wet lab experiments to only hexosyltransferase out of the potential seven glycosyltransferases. Analogously, they can focus their research on Muscular dystrophy, congenital, type 1D, out of several other diseases.

Arguably, the graph data model of RDF resources is more intuitive than the database schemas. In fact, the RDF data model enables us to model the inherent logical relations between entities that mirror the human cognitive model of the real world. Additionally, the RDF data model offers more flexibility than database schemas for accommodating changes to the underlying model.

Generalization

The integration approach demonstrated in this study can be generalized to more complex queries and to additional information sources. For example, many additional constraints can be easily added to the query presented earlier by exploiting other properties represented in GO or EG. Examples of such constraints include restricting the annotations to specific evidence codes (e.g., *TAS*) and narrowing the query to a specific model organism.

Only two resources are currently integrated in our RDF store. However, this approach can be generalized to other resources including pathway databases, microarray resources, disease ontologies and virtually all the structured knowledge bases currently under the umbrella of the Entrez system, including UniGene and HomoloGene. Knowledge extracted from unstructured sources such as the biomedical literature can also be integrated. Creating such an extensive repository of biomedical knowledge is one of the goals of the *Advanced Library Services* project under development at NLM.

Unresolved issues and challenges

In addition to scalability issues, which can be addressed by mature software and the next generation of hardware, challenges include the identification and organization of entities and relationships. Heterogeneous resources can interoperate in a RDF graph only if the entities shared by these resources are identified consistently. The namespace provided by the UMLS is expected to play an important role for the permanent identification of biomedical entities. In contrast to entities for which organizational schemes currently exist (terminologies and ontologies), the named relationships used to connect data entities during the conversion of EG from XML to RDF are currently not formalized in an ontology of relationships. As a consequence, only limited reasoning can be supported by the RDF graph. As sizeable ontologies of relationships become available, they too will be used for normalizing knowledge in our repository. RDF schemas and OWL will also be investigated.

Acknowledgments

This research was supported in part by the Intramural Research Program of the National Institutes of Health (NIH), National Library of Medicine (NLM) and by the Integrated Technology Resource for Biomedical Glycomics (5 P41 RR18502), funded by the National Institutes of Health National Center for Research Resources.

Building a Research Model for Human Genetic Variation Knowledge Management

Yulong Gu[a], James Warren[a]

[a] *Department of Computer Science, University of Auckland, Auckland, New Zealand*

Abstract

Organizational knowledge management (KM) research studies the nature of knowledge, the scope of KM, the factors and mechanisms that affect KM outcomes, as well as theoretical KM frameworks. This paper discusses the implications of past studies for the KM efforts in the human genetic variation (HGV) research domain and presents a HGV-KM research model. This model identifies the context of HGV KM studies, the predispositions and factors that may impact KM outcomes, and important KM processes. It also represents the relationships among these issues. Applying the model, further studies will point the way for improved capture and dissemination of HGV knowledge from routine HGV research activities to contribute to the global genetics knowledgebase.

Keywords:

Knowledge Management (KM); knowledge processing; human genetic variation (HGV) research; KM approach; KM framework; KM process; HGV-KM research model

Introduction

Knowledge Management (KM) theories

Knowledge is a fluid mix of framed experience, values, contextual information and expert insight; it includes both explicit knowledge that is transmittable in formal systematic language and tacit knowledge that has a personal quality and is hard to formalize and communicate [1-3]. Different views of knowledge lead to different perceptions of knowledge management (KM) [4, 5]. For instance, (i) if knowledge is an object or information access, KM should focus on building and managing knowledge stocks; (ii) if knowledge is a process, the focus of KM is knowledge flow and knowledge processing – knowledge creation, acquisition, codification, retention, storage/ retrieval, integration, coordination, transfer, sharing, distribution, application, valuation and use; (iii) if knowledge is viewed as an organizational capability, then KM centers on building core competencies, understanding the strategic advantage of know-how, and creating intellectual capital [6-8].

Human Genetic Variation (HGV) context

Human genetic variation (HGV) research aims to characterize the nature, distribution and evolution of genetic variations in humans and to study the relationship *between* genetic variation *and* environment in the origins *and* characteristics of human populations *and* causes, diagnoses, treatments and prevention of the disease; HGV scientists come from various domains, e.g. genomics, proteomics and clinical sciences [9]. The clinical and laboratory genetic services test and interpret the HGV of patients and/ or families [10]. There were over 500 HGV testing laboratories in the United States at 1997 [11]. The HGV testing is becoming a routine procedure in clinics and research, with at least 751 active laboratories and 936 clinical chemistry/ hematology centers at 2004 in the European Union alone [12]. An international survey at 2005 shows that 45% of early breast cancer patients discuss genetic testing with their physician and/or are referred to see a genetic counselor and 16.7% are then tested [13]. However, despite the significant growth of HGV knowledge, KM success is seldom reported:

i) for managing high-quality *knowledge stocks*. Enormous efforts are put into storing HGV data in Locus Specific Databases (LSDB) and general databases, such as HGVbase [14], UMD LSDB [15], OMIM Database [16] and the proposed Central Database plus WayStation Submission tool [17-20]. However, the validity of data in these databases is of some concern, possibly due to inadequate data curation [21, 22].
ii) for supporting *knowledge flow* and enhancing *knowledge processes*. For example, although HGV testing laboratories collect and produce a lot of data with HGV details, knowledge flow from these laboratories to HGV research community is not occurring often [10, 23].
iii) for building core *competencies* and creating *intellectual capital*. With no attempt to improve the present "pattern" [24] of knowledge processing in HGV research facilities, the research ability and intellectual capital are not being managed or changed by KM efforts.

With above KM problems, we apply KM theories to identify all the relevant factors; then, we develop a HGV-KM research model to present the anatomy among the significant issues.

Implications of past literature

We synthesize past literature from leading Organizational Management journals (e.g., Organization Science and Harvard Business Review), Information Systems (IS)

periodicals, (e.g., MISQ and ISR), HGV journals (e.g., Human Mutation and Nucleic Acids Research), KM or HGV proceedings and books, then present the significant implications in this section.

KM approaches in practice

Most recorded KM practice took the *product-centric* or *process-centric* approach, reflecting type (i) or (ii) KM focus [6]; however, *capability-centric* KM exercise (type three) is rarely reported. The *product-centric* KM manage knowledge as an objective organizational asset [4, 25]. It relies on the transformation of implicit or explicit knowledge from employees' heads to written information in documents and the subsequent management of these documents [26]. Accordingly, by using searchable document repository and content management systems [7], HGV knowledge can be captured, stored, retrieved and distributed in well-organized research documentations.

On the other hand, *Process-centric* KM views knowledge as residing with a person and/or a business process. It provides pointers to experts [25] and implements business process management [27], by adopting database of experts, decision aids and expert system, workflow management system, groupware, the systems supporting 'Community of Practice' and 'hardwiring' of social networks, etc. [6, 28]. HGV studies require profound knowledge on the subjects and methodologies. Therefore, research done around the globe is frequently referred; and international collaborations are often performed. Taking these natures of HGV research into account, the key to managing HGV knowledge is to share it among the researchers [26], applying process-centric KM. Meanwhile, such KM approach may trigger the benchmarking, reengineering and optimizing of the HGV research processes. By tracking and sharing HGV research activities, instance decision making in single variant interpretation may be transited into best practice in studying the gene. This transition may eventually enhance an HGV research methodology and become a valuable intellectual capital, since medical data analysis may discover new models, into which available knowledge could be incorporated [29]. Thus, approaches in managing HGV knowledge may take all product-, process-, and capability-centric endeavors.

KM frameworks in literature

Following KM approach review, this subsection extracts the implications of KM models as they offer best KM practices.

The result of knowledge creation, retention and transfer is affected by the properties of organization units, of unit relationships and of knowledge itself; and this effect is moderated by three key causal mechanisms – the three important KM processes: ability, motivation and opportunity [8].

Based on organizational capability perspective theory [30] and contingency perspective theory [31], two more preconditions for effective KM are discovered – the 'knowledge infrastructure capability' and 'knowledge process capability' – with the latter being influenced by contingent knowledge tasks [32].

Knowledge management systems (KMS) are a class of IS to manage organizational knowledge, and to enhance knowledge processes [6, 33]. Developed upon IS Success Model [34, 35], Figure 1 shows how the individual's and organization's performance at workplace are improved from using KMS [36-38].

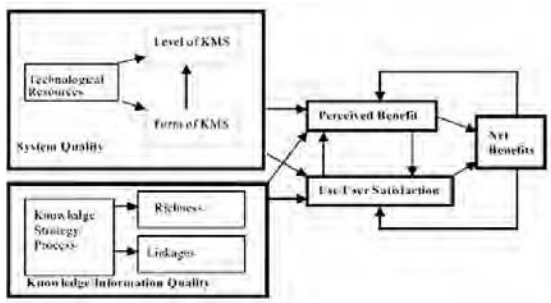

Figure 1 – KMS Success Model [36]

HGV-KM research model

To manage knowledge in HGV context, the practical questions are "which activities are the promising targets for KM support?" and "what are the nature and benefits of effective KM support?" An HGV KM study is to point the way for improved knowledge capture and dissemination from routine research activities to contribute to the global genetics knowledgebase. Drawing on past literature, we develop a research model (Figure 2) with nine significant KM issues: I. KM context, II. KM process, III. knowledge process capability, IV. contingent task characteristics, V. technology and system quality, VI. knowledge and information quality, VII. perceived benefits and user satisfaction, VIII. knowledge infrastructure capability, and IX. KM outcome. The construct relationships are direct impacts (as arrows from cause to result), moderating effects on a relationship's strength (by broken arrows) and weak connections (e.g. the quality of KM technologies as the extent to which knowledge processes and KM processes are computerized and integrated [36], represented by curves in the figure). In detail:

I. Context of a KM initiative or project [8]

According to [8], the predispositions of a HGV KM project include (i) the properties of units, e.g. a researcher's academic status and an organization's social status; (ii) the properties of relationships between units, e.g. the contact frequency between dyadic units and the connection pattern among multiple units; and (iii) properties of knowledge, including explicit HGV data and tacit know-how in HGV research, external and internal knowledge, and uniquely possessed and public knowledge.

II. KM process [8]

A KM process presents what a KM project offers and how well it functions to enhance an organization's (i) KM abil-

ity to codify implicit knowledge and produce information that makes sense to people other than the author [28], (ii) knowledge sharing motivation – the rewards and incentives, (iii) opportunity, and (iv) from process-centric KM perspectives, the management of HGV research activities and processes.

III. Knowledge process capability [32]

This organizational competency is the result of contextual factors and efforts (Constructs I and II) [8]; it then decides the quality of processed knowledge (Construct VI), according to product-centric KM theories and KMS Success Model [36]. It also has direct impact on overall KM effectiveness and this impact is moderated by knowledge-related tasks [32].

IV. Contingent knowledge tasks' characteristics [32]

The characteristics of knowledge tasks (such as task content and task domain) decide if the right knowledge is captured and used [38]. An example of task domain is about knowledge creation tasks that may belong to any of the four modes of socialization, externalization, combination and internalization [39]. The moderating role of this construct suggests that the KM efforts that precisely suit a task provide more effective results than those that don't [31, 32].

V. Technology and system quality [36]

In addition to the quality of general IS, such as 'ease of learning', 'integration of systems', and quick 'system response time' [34], KMS quality has three more dimensions: (i) the technological resources – the ability to develop, operate, and maintain a KMS, (ii) KMS form – the extent to which organizational memory and KM processes are computerized and integrated, and (iii) KMS level – the ability to bring past information to bear upon current activities [36, 37]. Given the teamwork nature of HGV research, quality KM technology should also support an HGV research facility's social capital (Construct VIII) by facilitating collaborations, distributed learning, knowledge mapping and opportunity generation [30, 40, 41].

VI. Knowledge and information quality [36]

High-quality knowledge and information are complete, accurate, current (of linkages), informative, rich in expression and in detail [34, 37]. For example, a valid HGV result has to offer reliable and sufficient evidence for variant interpretation based on accurate and unambiguous variant description.

VII. Perceived benefits and user satisfaction [36]

Perceptions on the benefits of KM technologies include perceived usefulness and ease-of-use, both of which are significant predictors of technology acceptance – the actual levels of system usage and user satisfaction [42]. This perspective of users is a result of knowledge quality; and it delivers ultimate KM outcomes in the organization [36, 38].

VIII. Knowledge infrastructure capability [32]

This capability represents the organization's social capital – the network of relationship; and it delivers KM results through knowledge sharing via the network [32]. It is operationalized by (i) technologies (Construct V), (ii) the organizational structure that provides the relationships (i.e. is an organization's property within Construct I) and (iii) the culture that provides a shared context (as a relationship's property in Construct I).

IX. Ultimate KM outcomes [36]

KM outcomes include the KM project-improved organizational effectiveness – such as the ability to innovate and coordinate [30] – and individual/organizational performance [38]. The individual KM performance, as measured by 'correctness of decision' and 'confidence in decision', will in turn have an impact on the organization's performance, e.g. on product quality [34, 36]. As a KM project's outcomes, the KM efforts may cause positive or negative consequences that will trigger more or less use of the knowledge and the KMS [38].

Discussion

From past KM approaches and frameworks that recorded the nature of knowledge, KM scope, KM factors and mechanisms, we identify nine categories of contextual,

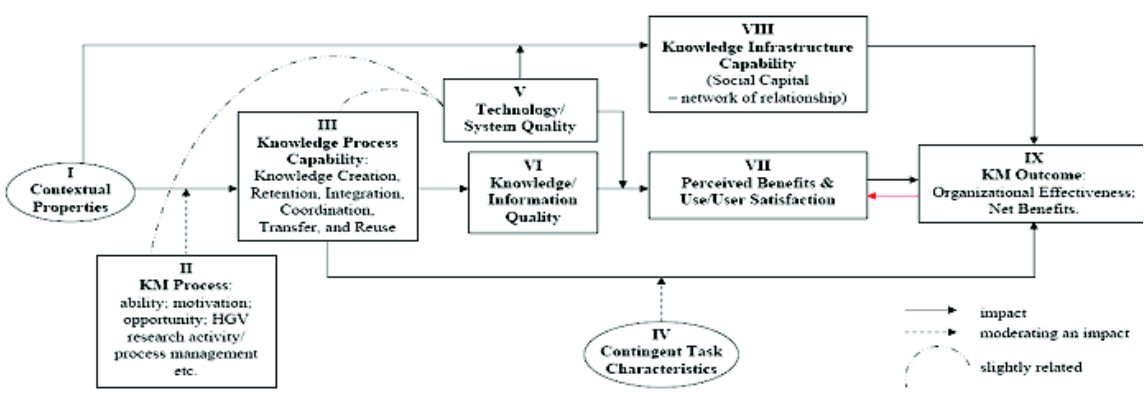

Figure 2 – HGV-KM Research model

cultural, structural, managerial, cognitive and technological issues that might be critical to the genetics research domain. Then we develop an HGV-KM research model presenting the dynamics among these nine constructs. There are a number of KM models proposed by both academics and practitioners that are not included in this paper, e.g. [43], [27], [24]. The reason for not covering them is that they focus more on single KM approach (product/process/capability-centric), but the HGV setting may have to apply all three strategies. Another limitation of our model is that it still needs validation, for instance, by empirical testing. However, it has revealed a promising research area that is to seek resolutions for the KM issues in genetics.

Our current research direction is to validate the model proposed herein through iterative action research. We plan to evaluate the impact of IT on various KM processes and capabilities, as well as on overall KM outcomes. This will also validate the model constructs and the model dynamics in terms of construct relationships; for instance, we are expecting to discover significant correlations between the features of a KM project (including implementation of a KMS) and resulting changes in KM performance. In addition to triggering more or less use of the knowledge and the KMS, feedbacks from KM effectiveness (Construct IX) might contribute to subsequent increases of user satisfaction, and possible establishments of KM-related organizational capabilities, and even changes in the contextual properties, such as the contact frequency and connection pattern in the social network. In conclusion, longitudinal studies on HGV KM practice may further refine our research model and add more insights on its anatomy.

Conclusion

Organizational knowledge management (KM) aims at effectively building and managing knowledge stocks, supporting knowledge flow and knowledge processes, building core competencies and creating intellectual capital. In the human genetic variation (HGV) research domain, KM efforts might improve the capture and dissemination of knowledge from routine HGV research activities to contribute to the global genetics knowledgebase. By synthesizing past literature, we have developed a KM research model with nine significant constructs; and we hope this paper will cast a light on future knowledge management research in the genetics domain.

Acknowledgments

We would like to thank many people for their support to this PhD project in the University of Auckland (UoA), especially the inspirational co-supervisor – Dr. Alexei Drummond, and our dearest colleagues Ms Karen Day, Dr. Martin Orr and Dr. Rekha Gaikwad. We are also indebted to Dr. Graeme Suthers, Prof. Andrew Shelling, Ms Deborah Prendergast, Ms Clare Stones and all the research students in the UoA Medical Genetics Group for their precious information and participation.

Abstract

This work aims at discovering the genetic variations of hemophilia A patients through examining the combination of molecular haplotypes present in hemophilia A and normal local populations using data mining methods. Data mining methods that are capable of extracting understandable and expressive patterns and also capable of making predictions based on inferences made on the patterns were explored in this work. An algorithm known as ECTracker is proposed and its performance compared with some common data mining methods such as artificial neural network, support vector machine, naive Bayesian, and decision tree (C4.5). Experimental studies and analyses show that ECTracker has comparatively good predictive accuracies in classification when compared to methods that can only perform classification. At the same time, ECTracker is also capable of producing easily comprehensible and expressive patterns for analytical purposes by experts.

Keywords:

datamining, classification, hemophilia A, genetic variations, haplotypes

Introduction

In this paper, we propose a new algorithm, called ECTracker[1], for pattern extraction and classification of a specific type of biological dataset known as haplotypes. A total of 47 patients affected by hemophilia A and 47 matched normal controls from Singapore were genotyped with a set of markers located on chromosome Xq28 which tags the hemophilia A disease gene. Hemophilia A is an X-linked recessive bleeding disorder that results from deficiency and/or abnormality of coagulation factor VIII (FVIII) [1]. The FVIII gene spans 186 kb of DNA and resides on 0.1% of the X chromosome (band Xq28).

We are interested in methods that are capable of performing the two tasks efficiently – first to extract expressive patterns for descriptive analysis, and second to perform classification. Intuitively, expressive haplotype patterns (or genetic variations) need to be extracted to provide medical practitioners with insights about the genetic manifestations of patients affected by hemophilia A. The extracted patterns are used for predictive inference (or classification) to help in carrier detection, which is useful for medical prognosis and decision making.

In this paper, we present the design and implementation of the ECTracker method. We also examine its performance as compared to common data mining methods in supporting the targeted tasks. Specifically, we compared the expressiveness of the haplotype patterns discovered using ECTracker with the haplotype patterns discovered using the Decision Tree method (C4.5). Furthermore, we also compared the classification predictive accuracy of ECTracker with existing classification methods including Artificial Neural Network, Naïve Bayesian Network, Support Vector Machine and Decision Tree (C4.5) [2][3].

The ECTracker method

There are two main steps in ECTracker. First, it identifies the genetic variations (or haplotype patterns) of hemophilia A patients to help analyze FVIII gene polymorphism for linkage analysis. Second, the haplotype patterns found in the first step are used to perform classification to facilitate carrier screening by medical practitioners. Details of the hemophilia A dataset will be introduced in the next section.

Step 1 – Finding interesting patterns

The first step of the ECTracker algorithm uses a level-wise neighborhood search method to enumerate all possible marker patterns of length one, two, and three etc, and then computes the statistical *odds ratio* of each of the patterns. Only those patterns that are significant are selected. The significance of a potential/candidate pattern is determined by computing its p-value. P-value calculates the probability due to chance alone of getting a difference larger than or equal to that actually observed in the data [4] [5]. A small p-value means it is difficult to attribute the observed difference to chance alone, and this can be taken as evidence against the null hypothesis of non-significance.

Odds ratio is a test statistic that has been widely used in the biomedical arena to measure the magnitude of association between two categorical variables based on some data collected [6] [7]. Given a pattern x, odds ratio computes the ratio of non-association between x and the label L, to the association between x and L based on a set of data. For example, given a pattern, say (1,3), and there are σ number of such pattern found in a dataset D associated with the class label *Abnormal* and π number of such pattern found in D associated with class label *Normal*. We are interested

1 Initial findings of this work were presented as a poster in *Asia-Pacific Conference on Human Genetics,* 2004.

in finding out whether the marker pattern (1,3) is strongly associated with the label *abnormal*. Table 1 shows the contingency table for our example where *P* is the number of samples in the dataset associated with the class label *Abnormal* and *N* is the number of samples in the dataset with class label *Normal*. The odds ratio is computed based on equation 1 defined below.

Table 1 – 2x2 contingency table

	Abnormal	**Normal**
not(*1,3*)	$P - \sigma$	$N - \pi$
(*1,3*)	σ	π

$$\text{Odds Ratio, } \theta = \frac{(P-\sigma)\pi}{(N-\pi)\sigma} \qquad (1)$$

Step 2 – Predictive inference / classification

The following describes the algorithm for predictive inference using the patterns derived from the previous step. Before presenting the algorithm, let us define the order of precedence of the derived patterns. This is used in selecting patterns for our classifier.

Definition: Given two patterns, r_i and r_j, $r_i >> r_j$ (also called r_i precedes r_j or r_i has a higher precedence than r_j) if

1. The p-value of r_i is less than the p-value of r_j, the smaller the p-value of a pattern the greater the statistical significance of that pattern.
2. Both patterns have the same p-values and $r_i \subset r_j$, the pattern length of r_i is shorter than the length of r_j. The pattern with shorter pattern length that can correctly classify an unseen case is preferred.
3. Both patterns have the same p-values and $r_i \not\subset r_j$, but r_i is generated earlier than r_j.

Let *R* be the set of patterns derived in step 1, and *D* be the training data used to derive *R*. The basic idea of the algorithm is to choose a set of high precedence patterns in *R* as our classifier. The classifier is of the following format: $<r_1, r_2, \ldots, r_n, default\_class>$, where $r_i \in R$, $r_a >> r_b$ if $b > a$. The *default_class* is the chosen class for an unseen case when no pattern in the classifier could classify the unseen case. The *default_class* can be selected by the user. However, if the user decides to let the classifier select the *default_class*, then the majority class in the data *D* will be chosen as the *default_class*.

The algorithm for building the classifier consists of five steps:

$$\text{Total score for class } C_x, \ \Omega c_x = \sum \omega_{C_x} \qquad (3)$$

Step 1: Sort the set of generated patterns *R* according to the relation ">>". This is to ensure that we will choose the highest precedence patterns for our classifier.

Step 2: For each pattern *r* in sorted *R*, if there exist another pattern *r*' such that the p-values of both *r* and *r*' are the same, and $r' \subset r$, then remove *r* from sorted *R*. This ensures that we choose the pattern with the shortest pattern length for each p-value.

Step 3: Select the first *n* patterns from sorted *R* following the sorted sequence to form the set $\Re$ for classification.

Step 4: Perform classification on the training data *D* using the *n* pattern classifier $\Re$ and compute the true positive rate of the prediction.

Step 5: If the true positive rate is less than the user defined minimum true positive rate, then repeat Step 3 and Step 4 with a different *n* value.

In classifying an unseen case in Step 4, the first pattern that satisfies the case will classify it. If no pattern applies to the case, a scoring method will be used for each of the classes, where the class with the highest score classifies the case. However, if the scoring method produces the same score for each of the available classes, then the unseen case will take on the default class. The user is able to set the default class to "unknown" to allow the classifier to make no prediction when no pattern applies to the case. This is useful when there are samples that are identical in attribute values but belonging to different classes. Figure 1 shows the pseudocode for scoring the classes.

1. for each class C_x do
2. $Score(C_x) = 0$
3. for each pattern $r_i \in \Re$ do
4. if $r_i.class == C_x$
5. compute ω_{C_x}
6. $Score(C_x) = Score(C_x) + \omega_{C_x}$
7. end
8. end
9. end

Figure 1 - Pseudocode for computing score of each class

For each pattern r_i in $\Re$ that classifies a class C_x, computes the individual pattern score using equation 2 as follows:

$$\text{Individual pattern score of } r_i \text{ for class } C_x, \ \omega_{C_x} = \frac{(nummatch)^2}{patternlength - casepatternlength} \qquad (2)$$

Where *patternlength* refers to the pattern length of r_i and *casepatternlength* refers to the pattern length of the case to be classified, and *nummatch* refers to the number of attribute matches between r_i and the case pattern. The total score for a class C_x is computed as shown in equation 3 as follows:

The unseen case will take on the class with the maximum Ω value. The objective of counting partial matches is for better noise handling.

We now describe how the scoring scheme handles noise with an example. Given that a pattern ABC is significant, its subset AB may or may not be significant since the odds ratio value is neither upward nor downward closed. However, if at a different odds ratio value, it is found that both ABC and AB are the shortest significant patterns for a class C1, this would mean that the attributes A and B are

important for determining the attributes for the class C1. Now, if we have some other patterns say ADE and DEF that are significant for another class C2. If we now have a case pattern to classify, say A, then A will have a higher score for class C1. This is the desired effect since the pattern ADE for class C2 may become significant due to noise, but it is less likely for AB and ABC to become significant due to noise.

The hemophilia dataset

A set of five common PCR-based polymorphisms located on chromosome Xq28 which tags the hemophilia A disease gene were collected and analyzed from 47 patients and 47 matched normal controls. The five polymorphisms collected are two microsatellite repeats in introns 13 and 22, and three Restriction Fragment Length Polymorphisms (RFLPs), namely BclI-intron 18, HindIII-intron 19, and XbaI-intron 22.The exact location of the markers are shown in Figure 2.

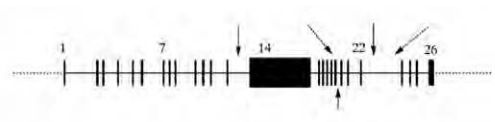

Figure 2 – Factor VIII gene

In the next sub-section, we describe the allelic frequencies of Factor VIII gene observed in our local population and the allelic frequencies reported by the authoritative resource website [8] for hemophilia A disease. The reporting of the allelic frequencies of our local population is useful for other medical practitioners not located in Singapore to decide whether they could make use of our discovery of the genetic variations for prognosis and counseling of their patients.

Allelic frequencies

The allelic frequencies observed in this study and those reported by *Hemophilia A Mutation, Structure, Test and Resources Site* [8] are tabulated in Tables 2, 3, and 4. Our results for *Bcl*I, *Hind*III, *Intron-13(CA)n* and *Intron22(GT)n(AG)n* are significantly similar to those reported in [35] with $\chi 2 < 3.841$ for *Bcl*I and *Hind*III, and $\chi 2 < 12.59$ for *Intron-13(CA)n* and *Intron22(GT)n(AG)n*. They are all within 95% confidence interval. However, the frequency for *Xba*I is significantly different from those reported by [35] with $\chi 2 > 3.841$.

Table 2 – Allelic frequencies of RFLPs

RFLPs	**Allele Frequencies (This Study)**		**Allele Frequencies (Reported by [35])**	
	(-)	(+)	(-)	(+)
	1	2	1	2
*Bcl*I	0.22	0.78	0.29	0.71
*Hind*III	0.78	0.22	0.75	0.25
*Xba*I	0.56	0.44	0.41	0.59

Table 3 – Allelic frequencies of Intron 13 (CA)n Repeats

	Allele Frequencies						
Intron 13 (CA)n Repeats	24	23	22	21	20	19	15
	1	**2**	**3**	**4**	**5**	**6**	**10**
This Study	0.01	0.10	0.06	0.26	0.52	0.04	0.01
Reported by [35]	0.013	0.05	0.11	0.29	0.45	0.07	0

Table 4 – Allelic frequencies of Intron 22 (GT)n/(AG)n repeats

	Allele Frequencies						
Intron 22 (GT)n/ (AG)n Repeats	31	30	29	28	27	26	25
	1	**2**	**3**	**4**	**5**	**6**	**7**
This Study	0.01	0.01	0.04	0.03	0.09	0.63	0.19
Reported by [35]	0	0	0	0.013	0	0.667	0.307

It was observed that samples with *Bcl*I-intron 18 allele 1 were always associated with *Hind*III-intron 19 allele 2 with $\chi 2$ p-value < 0.001. This is an expected observation as there are reported linkage disequilibrium between *Bcl*I and *Hind*III alleles from literature such as Ahrens et. al. [9] and EL-Maarri et. al. [10]. The *Hind*III marker was thus excluded since *Bcl*I and *Hind*III are in linkage disequilibrium, we could easily predict the value of the other attribute base on the value of one attribute, and hence 4 markers are sufficient in for the analysis.

It was further found that 70% of the samples had exactly the same allele values in all the markers in both patient and normal controls, which means that the 5 markers/attributes in the dataset is insufficient for separating 70% of the samples. After removing those samples whose disease and normal haplotypes cannot be distinguished, there are 28 samples remaining – 18 samples belonging to the disease phenotype and 10 samples belonging to the normal/control phenotype. Tables 5 and 6 show the frequencies of the disease and normal/control haplotypes respectively.

For descriptive analysis, we mainly report on the expressive and interesting patterns extracted from the remaining 30% of the dataset. Whereas for classification or predictive analysis, we divide the experiment into two parts: The first part compares the accuracies of the five classifiers based on the full hemophilia dataset. The second part we concentrate our study on the 30% of the dataset where those samples whose disease and normal haplotypes cannot be distinguished were removed.

Table 5 – Haplotype frequencies of probands with disease phenotype

Marker	Disease Haplotypes											Total
Intron-13 (CA)n	3	4	4	4	4	4	5	5		5	10	
*Bcl*I	1	2	2	2	2	1	2	2	2	1	2	
*Xba*I	1	1	1	2	2	1	2	1	2	1	1	
Intron-22 (GT)n/(AG)n	3	1	3	3	5	7	2	4	5	6	6	
No. of Probands	1	1	2	1	1	6	1	2	1	1	1	18

Table 6 – Haplotype frequencies of probands with normal/control phenotype

Marker	Normal/Control Haplotypes									Total
Intron-13 (CA)n	1	2	2	3	3	4	4	5	6	
*Bcl*I	1	1	2	1	1	2	2	2	2	
*Xba*I	1	1	2	1	1	1	1	1	2	
Intron-22 (GT)n/(AG)n	7	5	6	5	7	4	5	7	6	
No. of Probands	1	1	1	1	2	1	1	1	1	10

Results

Interesting pattern extraction

Expressive patterns derived by C4.5

C4.5 deduced that haplotype patterns (or genetic variations) of 4–*–*–*, 5–*–*–*, or 10–*–*–* (Intron13(CA)n–BclI–XbaI–Intron22(GT)n(AG)n) are highly associated with the disease phenotype. This derivation is not very useful as we could see from Table 6 that there are 3 probands with normal/control phenotype having intron-13 (CA)n allele values 4 and 5. Moreover, allele value 10 in intron-13 (CA)n only occurs once in the proband with disease phenotype (from Table 5), hence it is not able to give a generalize conclusion base only on allele value 10 of intron-13 (CA)n.

The possible reason for such a deduction by C4.5 may be due to the problem that the dataset is very small, and as a result the selection for partitioning attribute becomes biased for those attributes with more attribute values. Hence attributes with more attribute values will be assigned higher information gain as compared to attributes with fewer attribute values.

Expressive patterns derived by ECTracker

The longest most significant pattern associated with the disease phenotype derived by ECTracker is 4–1–1–7 (Intron13(CA)n–*Bcl*I–*Xba*I–Intron22(GT)n(AG)n). This is an interesting observation as the haplotype occurs in 33.3% of the disease phenotype and 0% of the normal/control phenotype with $\chi 2 > 3.841$ and odds ratio $\theta = 0$, which means that such observation occurs significantly greater than by chance. From Table 5, the haplotype occurs in 6 probands with disease phenotype as compare to other haplotypes which occur in no more than 2 probands. The shortest most significant patterns derived by ECTracker are 4–*–*–7 or 4–1–*–* with $\chi 2 > 3.841$ and odds ratio $\theta = 0$. This means that two markers alone were sufficient to define the disease haplotype, however, the longest most significant pattern provides a useful insight for the medical practitioners or scientists who seek to better understand the genetic variations of the disease.

This experiment shows that as compared to the decision tree approach of C4.5, ECTracker is capable of deriving useful patterns even when the dataset is very small.

Classification of the hemophilia A dataset

There are a total of 94 records in the hemophilia dataset, 47 records belonging to the class patient and 47 records belonging to the class normal. The classification methods that we examined include C4.5, Naïve Bayesian Classifier, Neural Network, Support Vector Machine and ECTracker. Except for ECTracker, all the other four classification algorithms are available from the package WEKA. WEKA is an open source data mining and machine learning software [2]. Table 7 shows the performance of various classifiers when applied to the full hemophilia dataset, and Table 8 shows the performance of the classifiers when applied to the pruned hemophilia dataset.

Table 7 – Analysis of classifiers based on full hemophilia dataset

	Accuracy	Precision of Class *Patient*	Recall for Class *Patient*	Precision for Class *Normal*	Recall for Class *Normal*
C4.5	71.43%	0.708	0.944	0.75	0.3
Naïve Bayesian Network	64.29%	0.7	0.778	0.5	0.4
Artificial Neural Network	78.57%	0.833	0.833	0.7	0.7
Artificial Neural Network	71.43%	0.75	0.833	0.625	0.5
Support Vector Machine	82.14%	0.842	0.889	0.778	0.7

Table 8 – Analysis of classifiers based on pruned hemophilia dataset

	Accuracy	Precision for Class *Patient*	Recall for Class *Patient*	Precision for Class *Normal*	Recall for Class *Normal*
C4.5	62.77%	0.615	0.681	0.643	0.574
Naïve Bayesian Network	62.77%	0.615	0.681	0.643	0.574
Artificial Neural Network	64.89%	0.675	0.574	0.63	0.723
Support Vector Machine	63.83%	0.623	0.702	0.659	0.574
ECTracker	67.02%	0.674	0.660	0.667	0.681

The classifiers were evaluated using 5-fold cross validation for the full dataset and leave-one-out for the pruned dataset. Since for each fold, different data samples are selected it is necessary run both steps in Section 2 fresh to avoid bias. Therefore, the patterns used for classification will vary for each fold.

ECTracker outperformed other classifiers with higher predictive accuracies on both full and pruned hemophilia A datasets.

On the full hemophilia dataset, the predictive accuracy of ECTracker is 67.02%, followed by Artificial Neural Network and Support Vector Machine with predictive accuracies of 64.89% and 63.83% respectively. Both Naïve Bayesian Network and C4.5 have the same predictive accuracy of 62.77%.

On the pruned dataset, ECTracker was able to accurately predict the phenotype of a sample given its polymorphic markers 82.14% of the time, followed by Artificial Neural Network at 78.57% of the time. C4.5 and Support Vector Machine were able to make accurate predictions 71.43% of the time.

There are 94 records in the unprune hemophilia A dataset, which is reasonably large, and there are 23 records in the pruned hemophilia A dataset which is rather small. Our experiments show that ECTracker is capable of providing good classification accuracy on both small and large datasets when compared to other classification methods.

Conclusion

In this work, we explored methods that are capable of extracting understandable and useful patterns, and also capable of performing inference on the patterns to make prediction. We applied these methods to find the genetic variations of a real dataset consisting of patients affected by hemophilia A to facilitate haplotype analysis by medical practitioners. We examined the issues of descriptive and predictive analyses using our proposed method called ECTracker.

In descriptive analysis, ECTracker is capable of extracting comprehensible and useful patterns from the hemophilia A dataset. Comparing with the patterns derived by C4.5, the patterns derived by C4.5 are less useful, as described earlier.

In predictive analysis or classification, ECTracker is capable of producing good predictive accuracies in classification that are comparable to those methods that only perform classification such as Artificial Neural Network and Support Vector Machine.

The experiments have indicated that ECTracker is potentially an effective method for both pattern extraction and classification for biomedicine in particular, and datamining in general.

The approach proposed here provides analysis and classification based on mainly the disease status of an individual. Continuously distributed quantitative traits such as blood pressure and choltesterol level may also be of significance to the clinicians. ECTracker can be extended to perform analysis and classification based on continuously distributed quantitative traits by defining a new scoring method for the interesting patterns. Further investigation will need to be done to assess the feasibility of such extension.

A Dynamic Query System for Supporting Phenotype Mining in Genetic Studies

Angelo Nuzzo, Daniele Segagni, Giuseppe Milani, Carla Rognoni, Riccardo Bellazzi

Department of Computer Science and Systems, University of Pavía, Pavía, Italy

Abstract

This paper describes an information technology infrastructure aimed at supporting translational bioinformatics studies that require joint management of phenotypic and genotypic data. In particular, we integrated an electronic medical record with an open-source environment for data mining to create a flexible and easy to use query system aimed at supporting the discovery of the most frequent complex traits. We propose a logical formalization to define the phenotypes of interest; this is translated into a graphical interface that allows the user to combine different conditions relative to the electronic medical record data (e.g., the presence of a particular pathology). The phenotypes are then stored in a multidimensional database. Then, the data mining system engine reads the filtered data from the database and executes dynamic queries for analyzing phenotypic data, presenting the results in a multidimensional format through a simple web interface. The system has been applied in a study on genetically isolated individuals, the Val Borbera project.

Keywords:

phenotype mining, complex traits, intelligent query, clinical data warehouse.

Introduction

A specific characteristic of the post-genomic era will be the correlation of genotypic and phenotypic information [1][2]; the emerging discipline of Biomedical Informatics may provide knowledge and tools for dealing with such an ambitious goal [3]. In this context, the studies aimed at the so-called genetic dissection of complex traits represent a first crucial benchmark for Biomedical Informatics and for translational bioinformatics.

The definition of an Information Technology infrastructure to support this kind of studies, and in particular the studies aimed at the analysis of large sets of phenotypes to discover the most prevalent diseases and then to integrate genotypic information, is a challenge which can be considered a paradigmatic goal of Biomedical Informatics. As a matter of fact, research on phenotypes requires the definition of an architecture for data collection, the implementation of an electronic medical record, the development of a system for the definition of the phenotypes of interest, and the design and implementation of a data warehouse system for analyzing phenotypic data. Moreover, selecting which are the phenotypes of interest determines the subsequent genotyping choices, especially when a genome-wide scan is not feasible or suitable.

Once clinical data are collected, it is crucial to perform a series of queries and data aggregation steps to characterize the population and extract the most prevalent phenotypes. However, clinicians, biologists and epidemiologists are usually unable to explore the collected information, because the use of general query languages requires substantial technical skill, as well as knowledge of the underlying database structures. On the other hand, the need of performing "dynamic" queries hampers the implementation of a "standard" user interface for pre-defined queries. To address this problem, we are defining a dynamic query system based on data warehouse and mining concepts. The clinical data are copied into a data mart oriented to data analysis. Thanks to the integration in the overall system of open-source environment for data mining it is possible to design a simple interface for performing aggregation, counting and simple statistics on the majority of the variables contained in the clinical database.

The implementation of the system has a number of steps which follows a workflow targeted at identifying the most important phenotypes which characterize a particular population. Such workflow includes the following steps:

1. The development of a relational database collecting clinical data on the target population
2. The translation of the database structure into a multidimensional data-base (data mart) oriented for query and reporting
3. The formal definition of the phenotypes to be searched and studied and their mapping in the database
4. Finally, the design and implementation of the data mining tool to easily extract the phenotypes and analyze their relationships

The aim of the paper is to describe the IT infrastructure of the system and the biomedical informatics challenges we are dealing with. Preliminary results on the use of the system to support a study on genetically isolated individuals, the Val Borbera project [4], will also be reported.

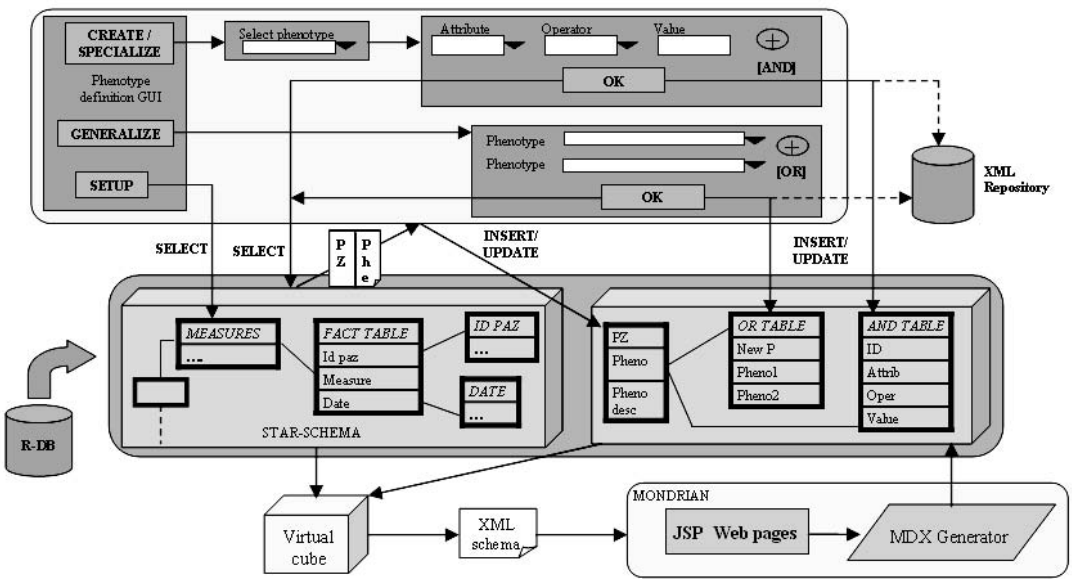

Figure 1 - Overview of system's components an the interactions among the 3 layers

Materials and methods

Objective

The final purpose of the system that we have developed is to provide a versatile and easy to use data inspection tool to identify which phenotypes may be more successfully investigated in the population under study, so that suitable genotyping choices may be made subsequently. The system accomplishes this purpose by providing tools for two main tasks:

1. for formally define the phenotypes to be investigated by a graphical user interface
2. for exploring clinical data to extract and analyze individuals with the same phenotypes (as they have been previously defined)

Both aspects can be performed in a database where the information is stored in a non-normalized data structure, which is often referred to as data mart. As a matter of fact, while a normalized structure is always required for correct management of the database (as it concerns data security, integrity, reliability), the database is greatly facilitated by the use of query-oriented data schema. That's why the basic common layer of our implemented system is a non-normalized data structure, the so-called "star schema", to which the two developed applications for query definition and data assessment are interfaced. Details of the components and their interactions are described in the following paragraphs, while a global overview is given in Figure 1.

From the relational DB to the "star-schema"

The typical data structure that has become a standard for all data warehouse applications is a multi-dimensional model called the "star join schema". Unlike the Entity-Relation model, the dimensional model is asymmetric. There is one large dominant table in the center of the schema, called the fact table. It is the only table in the schema which is connected to the other tables with multiple joins. Such other tables, called the dimensional tables, only require a single join to be referenced by the fact table [5].

Typically a clinical database can be modeled by a star schema in which each record in the fact table represents a combination of a clinical measure and its values on a specific date for a specific patient. So the dimensions are individuals, measurement time and measurement values: all of them can be further specified using a snowflake model[1].

The adaptation of the star-schema and of the snowflake models to the clinical context requires however several efforts. In fact, when taking into account the phenotype information in the analysis, we cannot model it as a dimension of the fact table, because it would be a *non-additive* dimension with respect to the others. *Additivity* is the ability to use an aggregate operator (summation, counting, average) along the dimensions of the same fact [6]: in our case, the phenotype dimension would be additive only along the patient dimension, but not along the others (measurements and time), as it is defined by a set of measurements. To overcome this problem, we have defined a new fact table to model the relationship between phenotypes and individuals.

The star schema and the phenotype tables are the physical models of the new multidimensional database. They represent two multidimensional "cubes" that together form the logical model of the database. The cubes may be merged in a single "virtual" cube, so that it is possible to use an Online Analytical Processing (OLAP) engine to perform

1 A *snowflake model* is a model in which a given dimension has relationships to other levels of the same dimension. It is used to re-normalize complex dimensions to eliminate redundancy.

data analysis (described in detail in the following paragraphs).

The phenotype definition tool

Clinicians and biologists usually define a phenotype by a set of variables and the values they may take. In order to select (and then to analyze) the individuals satisfying that set of rules, it is necessary to write a suitable SQL statement to run a query to retrieve them. However, as the users may have no expertise in the use of a query scripting language, we provide a tool that automatically generate the proper SQL script to select individuals with the defined phenotype.

To perform this task, a formalization of the phenotype definition is needed. The basic assumption is to consider a phenotype as a set of conditions in the form of attribute/value pairs. Then using logical operators (AND, OR) it is possible to combine different conditions to define more and more complex phenotypes. In particular, the AND operator allows the specialization of a defined phenotype, while the OR operator is used to merge different phenotypes into a single, more comprehensive one. This procedure corresponds to a logical tree construction, in which the nodes are the conditions, the AND operator is used to go from the top to the bottom and the OR operator is used to add an upper node from the bottom to the top (figure 2).

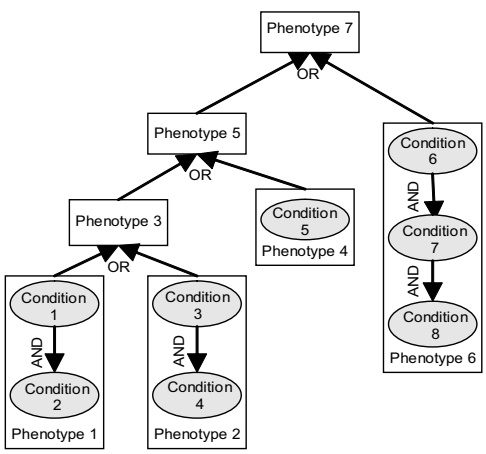

Figure 2 - Formalization of the phenotype definition

The limitation of this model is that it is not possible to define any kind of AND/OR combination of the conditions under investigation, as in the corresponding SQL string, it will not be possible to interpret the correct order of the subgroups (i.e., the correct position of brackets in the query string). So it is necessary to define the AND-conditions first, and then combining them using the OR operator.

The end users can create these definitions using a graphical wizard developed in the JAVA programming language. It interacts with the two sections of the non-normalized database, i.e., the star schema of the clinical data and the phenotype definition tables. The wizard is automatically setup by reading an XML file in which the two data structures are encoded. The conditions (attributes and their values) may be defined by combo boxes, which provide lists of attributes according to the measures table of the star schema, suggesting the admissible ranges of values for each attribute. Once the rules are defined, the corresponding SQL string is created by merging conditions by AND operators, in order to: i) store the rules in the phenotype section tables, and ii) select the subgroup of individuals satisfying that conditions and storing the relation individuals-phenotype. In the same way, it is possible to choose another graphical panel to selected some defined phenotypes to be merged together by the OR operators to create a new phenotype, which is stored in the phenotype section.

The data analysis tool

Dealing with clinical data to analyze phenotypic information implies taking into account heterogeneous data and viewing them at the same time. This means that it should be possible to perform a multidimensional inspection of the dataset. Whereas a relational database stores all data in the form of rows and columns, a multidimensional dataset consists of axes and cells organized in multidimensional "cubes", the dimensions of which are the directions of drill-down investigations.

The technique of multidimensional analysis is implemented in software tools called online analytical processing (OLAP) engines., OLAP, in fact, means analyzing large quantities of data in real-time. Unlike Online Transaction Processing (OLTP), where typical operations read and modify individual and small numbers of records, OLAP deals with data in bulk, and operations are generally read-only. The term "online" implies that even though huge quantities of data are involved — typically many millions of records, occupying several gigabytes — the system must respond to queries fast enough to allow an interactive exploration of the data.

As described above, the logical model of the star schema and the phenotype tables consist of two virtual cubes that may be merged in a single one, which is the input for the OLAP engine. In our system we use an OLAP engine written in the Java programming language: Mondrian [7]. It executes queries written in the MDX language (that has actually become a standard for data warehouse applications) [8], reads data from a relational database, and presents the results in a multidimensional format through a Java API, so that the presentation layer may be chosen by the final user. JSP pages are provided by default, so that the user can simply use a web browser for data visualization. The MDX queries have to be defined by the user, so we have developed a specific module (the "MDX generator" box in figure 1) that automatically create the MDX scripts directly from the attributes of interest chosen by the check box lists of the main page.

Sharing and generalizing issues

In order to make the graphical wizard usable on different databases, it has been made configurable via an XML file containing the star schema description. So the only prereq-

uisite for using it is to provide a star schema that is compliant to the model described above. Then the phenotype tables are automatically generated and populated by the GUI. Moreover, the phenotype definitions are also stored in XML files, so that existing phenotypes loading is performed by reading the XML files instead of the tables, and the XML repository may be shared with other scientists interested in analogue analysis. On the other side, whichever OLAP engine will be chosen, the only manual task needed is to code the virtual cube in the specific format required as input by the engine. Using Mondrian, it means to create the XML file containing the definition of the cube.

Results

The tools described in the previous section have been tested for the exploration of the clinical database of the Val Borbera genetically isolated population project [4]. This study is conducted in collaboration with the DIBIT of San Raffaele Scientific Institute of Milan, for which we have provided the architectural IT infrastructure for data collecting and storing. The clinical data have been collected in a relational database in a high normal form, actually containing about one hundred clinical measures relative to more than 4000 individuals. So the first step was to create the correspondent star-schema for the multidimensional analysis. Here we present an example regarding the analysis of dysfunctions related to the thyroid.

Phenotype definition

Before the use of a multidimensional analysis approach, the biologists had to ask a technician to extract individuals with the traits of interest by writing the SQL statement to be executed on the relational database. The statements are often some hundreds of lines long, due to the large number of join to be performed. Using the developed infrastructure, in contrast, the user has only to define the conditions by the graphical window shown in figure 3, that will be merged by the AND operators. The combo box are automatically filled in by reading the XML file in which the star schema is encoded.

Figure 3 - Creation/specialization panel

The defined phenotypes are summarized in the main panel of the GUI. The phenotype list shows the XML files that have already been created; details of the rules applied to define it are given below by selecting one of them (figure 5).

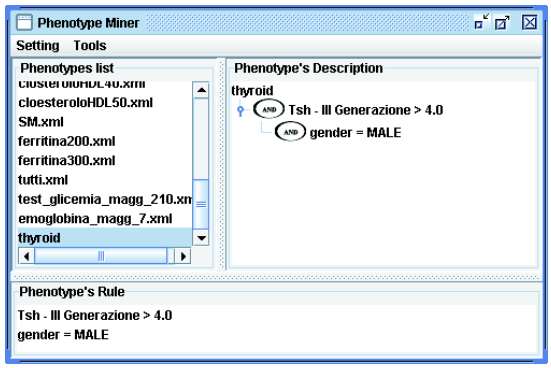

Figure 4 - Main panel: existing phenotypes are shown and details for the selected one

So if the user wants to specialize an existing phenotype, he can select it from the "Phenotype's Rules" window (figure 3) and add conditions using the AND operators.

Otherwise, if some defined phenotypes have to be merged together by OR operators to create a new phenotype definition, they can be selected using the "generalization panel", as shown in figure 4. In this case the combo box are filled by reading the XML phenotype files stored in the suitable repository.

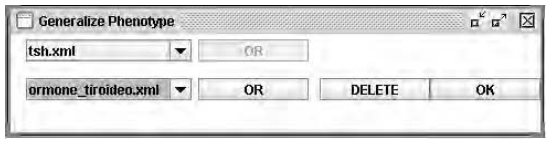

Figure 5 - The generalization panel

In both cases, the selection of individuals with the specified phenotypes is performed, and the relations are stored in the proper table. So the phenotype becomes a dimension which can be used to explore individual's data.

Data analysis and validation

When the OLAP engine starts up, it reads the XML file containing the cube definition. The first page shows a set of check boxes containing the fields of the underlying tables, so that the user may choose the variable to be investigated (the phenotypes are among them). Once the features have been chosen, the engine loads information related to the individuals having that phenotype. Then a visual inspection of the measurements values can be done expanding or collapsing cells of the resulting table, so that the analysis can be executed at different levels of detail (figure 6). Automatic graphical reports can also be generated.

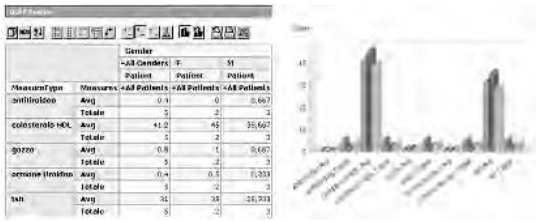

Figure 6 - The resulting dynamic table provided by Mondrian: the user may expand or collapse the cells to view the data at different levels of detail

A first validation of the system is now undergoing; it consists of verifying how it improves the phenotype searching process. Biologists formulate several verbal requests, we then compared the results obtained by themselves using the system and the ones obtained by a technician performing a SQL statement (which is typically quite a lot of instruction lines long). The first initial report table is always the same for both tasks and for any condition exploited (many different phenotypes corning thyroid diseases, hypertension and diabetes have been defined and searched): this means that the query editor correctly runs. The advantage provided by the OLAP engine is then the capability of allowing a dynamic interaction with the data to perform a more detailed exploration.

Conclusion

Current genetic studies are characterized by the collection of huge quantity of both clinical and genotypic data. The final goal of such effort is the "genetic dissection" of complex phenotypes; the first challenge of data analysis is therefore to identify which phenotypes must be investigated. However, this task may be difficult to be performed using "standard" tools for database navigation, such as SQL query, as they require technical skills for the end user to extract interesting information. In order to solve this problem, in this paper we present a dynamic query system based on data warehouse and mining concepts, which allows phenotypes definition by a graphical user interface and data exploration using OLAP tools. Both applications are based on a common underlying data layer, the structure of which is a data mart oriented to data analysis. The phenotype definition is based on a logical formalization and it is properly stored to be processed by the OLAP engine. Once the phenotypes have been defined, the OLAP engine allows the user to perform a visual inspection of the data through a set of results dynamically created. We have chosen an open source OLAP engine, Mondrian, and we integrated it with new components (the MDX generator) in order to automate other specific technical operations.

All the modules of the system are configurable via XML files, so that they can be reused to analyze other clinical databases. The only requirement is to translate the data structure into the data mart described in this paper, and to codify it in an XML file. Moreover, the phenotype definitions are also stored in an XML repository, so they may be reused and shared with other users to compare results.

The system as been tested on a real dataset, the clinical database of the Val Borbera project, showing that it is easy to use and time-saving. Future development of the system will improve the graphical user interface. The phenotype definitions will be shown by graphs, corresponding to the logical model used to create it, so that the user may expand it directly by adding or removing nodes.

Acknowledgments

We gratefully acknowledge Cristiana Larizza for software development supervision and DIBIT group (D. Toniolo, C. Sala, C. Camaschella) for providing data of the Val Borbera project.

Identifying QT prolongation from ECG impressions using Natural Language Processing and Negation Detection

Joshua C. Denny, MD[a,b], Josh F. Peterson, MD[a,b]

Departments of [a]Biomedical Informatics and [b]Medicine, Vanderbilt University Medical Center, Nashville, TN, USA

Abstract

Electrocardiogram (ECG) impressions provide significant information for decision support and clinical research. We investigated the presence of QT prolongation, an important risk factor for sudden cardiac death, compared to the automated calculation of corrected QT (QTc) by ECG machines. We integrated a negation tagging algorithm into the KnowledgeMap concept identifier (KMCI), then applied it to impressions from 44,080 ECGs to identify Unified Medical Language System concepts. We compared the instances of QT prolongation identified by KMCI to the calculated QTc. The algorithm for negation detection had a recall of 0.973 and precision of 0.982 over 10,490 concepts. A concept query for QT prolongation matched 2,364 ECGs with precision of 1.00. The positive predictive value of the common QTc cutoffs was 6-21%. ECGs not identified by KMCI as prolonged but with QTc>450ms revealed potential causes of miscalculated QTc intervals in 96% of the cases; no definite concept query false negatives were detected. We conclude that a natural language processing system can effectively identify QT prolongation and other cardiac diagnoses from ECG impressions for potential decision support and clinical research.

Keywords:

electrocardiogram, Unified Medical Language System, natural language processing, concept identification, decision support.

Introduction

Electrocardiograms (ECG) provide significant medical information that has been largely untapped in medication decision support interventions. ECGs are commonly used to help diagnose cardiac diseases such as myocardial infarction and ischemia, arrhythmias, and cardiomyopathies as well as some extracardiac diagnoses. Recent studies have highlighted the risk of sudden cardiac death due to medications known to increase QT intervals [1, 2]. Medications can also affect the risk of myocardial infarction [3, 4], induce second and third degree atrioventricular block [5], and cause other, potentially fatal, arrhythmias [1]. A decision support system that warns providers when prescribing medications to patients with existing risk factors, such as QT prolongation or atrioventricular block, may be valuable in guiding prescription choice.

QT prolongation is a key risk factor for development of Torsades de Pointes, a potentially fatal cardiac dysrhythmia. Since the QT interval, the measurement of the time between ventricular contraction ("QRS complex") and its repolarization ("T wave"), varies with heart rate, QT prolongation is typically assessed via a QT corrected for rate (QTc) [6]. A value greater than 440-460 ms is typically considered prolonged. Many drugs are known to prolong the QT interval; it is the most common reason for a drug to be removed from the market [2, 7]. However, many other factors can influence measurement of the QT (and thus QTc), including arrhythmias, intraventricular conduction disturbances, ECG measurement technique, and morphological changes in the ECG.

ECG findings consist of two types: morphologic descriptions (e.g., QT prolongation or widened QRS) and interpretations of those findings (e.g., myocardial infarction, atrial fibrillation, or ventricular hypertrophy). While many have developed automated feature extraction programs based on ECG waveforms, automated algorithms are imperfect, with accuracies of 42-96% [8, 9]. These algorithms are generally superior for morphological descriptions than their interpretations [8, 9]. However, many factors, such as an arrhythmia or ischemia, can alter the accuracy of morphological descriptions as well. For these reasons, cardiologists' interpretations of ECGs remain the consensus gold standard [8, 10, 11].

Natural language processing and concept-based indexing to standardized vocabularies such as the Unified Medical Language System (UMLS) have been applied to radiology reports [12, 13], clinical notes [14, 15], and medical education documents [16], among others. Previously, we reported the use of the KnowledgeMap concept indexer (KMCI) to identify UMLS concepts from cardiologist-generated ECG impressions [17]. KMCI is a general purpose concept identifier, using rigorous, scored-based algorithms to identify concepts from free text [16]. It accurately identifies unknown abbreviations, acronyms, and underspecified concepts (e.g., document phrase "1st degree block" for the closest UMLS match "1st degree *atrioventricular* block"). KMCI scores ambiguous concept matches using the context of other concepts matching around it to favor candidates that are likely to co-occur. Previously, we optimized and evaluated its performance on ECG impressions, finding a recall of 0.90 and precision of 0.94 [17]. It was especially accurate for myocardial perfusion changes, ECG rhythms, and extracardiac manifestations (recall and precision in excess of 0.98). This system, however, did not have the ability to detect negated or possible findings.

Table 1 – Comparison of KnowledgeMap Concept Identifier (KMCI) identification of negation to gold standard physician review

	Gold standard		
KCMI	Negated or possible findings	Positive or Probable findings	**Total concepts**
Identified as negated or possible	722 (6.9%)	13 (0.1%)	735 (7.0%)
Identified as positive	20 (0.2%)	9725 (92.8%)	9745 (93.0%)
Total Concepts	742 (7.1%)	9738 (92.9%)	10480

In this paper, we report on the integration of negation detection algorithms into KMCI and its initial application on a four-year collection of ECGs to identify QT prolongation. The ultimate goal is a codified database of ECG impressions for the development of a medication decision support system.

Methods

Creation of ECG database

Vanderbilt University Medical Center has developed an anonymized database of all orders, laboratory results, and ECGs for all inpatients admitted for 2-30 days from 1999-2003 as part of an ongoing research study investigating drug effects. The ECGs were imported in an XML format from an ECG management system. Every ECG includes machine calculated intervals and heart rate as well as a cardiologist-generated free-text impression. Cardiologists create an impression for all ECGs by selecting among personalizable stock phrases ("normal sinus rhythm") and editing as necessary ("normal sinus rhythm *with rare PVCs*"), or typing comments *de novo* ("LA abnormality, PVCs, and inferolat ST-T changes"). Finally, cardiologists code each ECG with a standard severity: normal, otherwise normal, borderline normal, or abnormal. We extracted all ECGs from our research repository and loaded them into a relational database. There were 44,808 ECGs in the database with more than 155,000 sentences.

From this dataset, we randomly selected a test set of about 5,000 sentences for development of our negation algorithm. Another 5,000 randomly selected sentences were reserved as a validation set. All subsequent data analysis was performed on the entire dataset of ECGs.

Negation tagging algorithm and evaluation

Many authors have developed negation tagging algorithms [18-20]. We applied a modified version of the NegEx algorithm [18] using regular expressions. We marked phrases as "negated", "possible", or "asserted." For the purposes of decision support, we included findings indicated as "probable" or "likely" as asserted findings. We used a total of 205 phrases indicating negation or possibility, including symbols such as "?" and "r/o" as indictors of "possible." We used a window of 8 words before or after a negating phrase. In this dataset, we found that most periods marked abbreviations rather than sentences. Semicolons, unmatched closing parentheses, and other negating phrases terminated the current negation window.

One author (JP, an internist), unfamiliar with the NegEx algorithm or its implementation, scored 5000 sentences from randomly selected ECGs via a color-coded HTML interface that highlighted the negating phrase and words modified by them. Only medical concepts or medical modifiers were considered for scoring. Concepts were marked as a correctly identified negated concept (i.e., a true positives, TP), false positives (FP), true negatives (TN), and false negatives (FN). We calculated recall of negated concepts as TP/(TP+FN); precision as TP/(TP+FP); and negative predictive value, the probability that the concept is not negated (i.e., an asserted finding), as TN/(TN+FN). Following the evaluation, three new negation phrases were added and validated over several thousand sentences with an improvement in matching before application to the entire dataset.

Development of concept-based ECG database

We applied KMCI to identify Unified Medical Language System (UMLS) concepts from the free text ECG impres-

Table 2 – Concepts employed to identify QT prolongation within ECG impressions.

Concept query (Asserted and Possible Concepts only)				**ECG matches**	**True Positives**
1	C0151878 Prolonged QT interval			2294	2193
2	C1560305 Prolonged QTc interval			55	55
3	C0023976 Long QT syndrome			2	2
4*	C0429028 QT interval C0489625 QTc interval C0860814 QTc	with any of	C0205166 Long C0439590 Prolonged C0392744 Lengthened	100	100
Total unique ECGs				**2,364**†	**2,363**†

*For query 4, one concept from each list must occur within the same sentence to be considered a match.
†Some ECGs matched more than one concept query (e.g., "QT prolongation. Compared with [date], the QT has lengthened.")

Table 3 – Comparison of QT prolongation identified in ECG impression to automated QTc by ECG machine.

	Concept query	QTc > 400	QTc > 450	QTc > 500	QTc > 550
ECGs matching criteria	2,364	34,059	11,804	2,518	620
KMCI positives	2,364	2,357	2,304	539	117
Sensitivity		1.00	0.98	0.23	0.05
Specificity		0.19	0.77	0.95	0.99
Positive predictive value		0.06	11,804	2,518	620
Negative predictive value		1.00	0.20	0.21	0.19

sions, using the optimizations identified in prior study [17]. We added synonyms and derivational transformations to KMCI's lexicon and modified the sentence-identification algorithm to ignore most spaces and periods when determining sentence breaks. We used the 2006AC version of the UMLS [21]; the only restriction on concept matching is favoring underspecified concepts with words such as "heart" and "electrocardiogram" (see [17] for a full list). Candidate UMLS concepts with these words are penalized less than candidates with other words when the words do not match a document word. We applied the negation algorithm following the concept identification step to mark each concept as positive, possible, or negated. The concept-identified ECGs are linked to the original ECG impressions and calculated intervals, forming the identified ECG dataset.

Analysis of QT prolongation

Through perusal of the ECG dataset, the authors identified the UMLS concepts representing "QT prolongation," including any text indicating a probable or possible QT or QTc prolongation. To verify that we had found all concepts representing QT prolongation, we also did text searches for all string matches with "QT" or "QTc." Each was manually verified by analyzing all unique strings containing the concept. We extracted these concepts, ignoring negated concepts, along with the automated QT and QTc intervals identified by the ECG management system. We compared the predictive value of the computer calculated QT and QTc intervals (a continuous number) via the area under the receiver operator characteristic curves (AUC) using the cardiologist interpretation as the gold standard and also by the positive predictive value of the commonly-used cutoff values of 400ms, 450ms, 500ms, and 550ms.

To assess the negative predictive value of our query, we reviewed a random sampling of 100 ECGs with calculated QT or QTc intervals > 450 for potential reasons why the QT calculations may be incorrect and to ascertain if any positive ECGs were missed by our concept query. Since the ECG images are not stored in our anonymized database, we were only able to evaluate the ECG intervals and raw text of the cardiologist impression. Student t-tests were used to compare parametric data. AUC and statistical analyses were performed with Stata, version 9.2 (StataCorp LP, College Station, TX).

Description of identified ECG database

To investigate the possibility for the database for decision support, we developed preliminary queries for a number of diagnoses that may be of interest for decision support (see Table 4). Each of these topics requires an interpretation of the free text. Topics were selected by finding the UMLS concepts representing the topic of interest in the database of matched concepts. For myocardial infarction, this involved the tree of concepts related to "myocardial infarction" and "infarct."

Results

Table 1 shows the results of the negation analysis. The 5,000 sentences in the negation test set contained a total of 10,480 UMLS concepts. Overall recall was 0.973 and overall precision 0.982. The negative predictive value of finding negation (probability that a statement was positive given it was identified as positive) was 0.998. All false negatives were due to three phrases not present in the regular expression list: "replaced <negated concept>", "<negated concept> replaced by", and "<negated concept> is/are gone." Several of the false positives were instances in which negating phrases were amid multiple concept words (e.g., "ST *no longer* depressed," in which the negated concept "ST depression" is separated by the negation phrase "no longer"). KMCI typically identified the correct UMLS concept for these phrases. Misspellings also caused some errors.

KMCI identified 375,838 concepts from the 44,080 ECGs in the database mapping to 23,080 unique admissions. Cardiologists identified 70% percent of the ECGs as "abnormal," 12% as "borderline," and 18% as "normal" or "otherwise normal." Of identified concepts, 339,554 (90.3%) were asserted, 29107 (7.7%) possible, and 7177 (1.9%) negated.

Table 2 shows the concepts used for the QT prolongation query and frequency of each in the database. There were 254 unique strings with a range of 2-18 words (median 11 words, weighted median 5 words) matching the QT prolongation query; 15 of these (e.g., "QT interval long for rate") accounted for nearly 90% of all matching impressions. The overall precision was 2363/2364 (1.00). Table 3 shows the results of different methods of predicting prolonged QT intervals; 2,364 ECGs (5.3% of all ECGs) were identified as representing QT prolongation by our concept query. The average QTc interval for those with prolonged QT intervals was 487 ms (range 363-716 ms); ECGs without mention of QT prolongation averaged 429 ms ($p<0.001$, range 46-785 ms). Overall, the calculated QT interval had an AUC of 0.73 for predicting QT prolonga-

Table 4 – Number of ECGs expressing potential targets for decision support

Concept	Total (%)	Positive	Possible	Negated
Myocardial infarction (MI)	6,355 (14)	3,381	2,919	55
Acute MI	208 (0.5)	167	36	5
Myocardial ischemia	2,312 (5.2)	1,855	444	13
ST segment elevation	1,015 (2.3)	895	92	28
Wolff-Parkinson-White bypass tract	107 (0.2)	93	7	7
Atrioventricular block, 1st degree	2,461 (5.5)	1,876	571	14
Atrioventricular block, 2nd degree	61 (0.1)	58	1	2
Atrioventricular block, 3rd degree	24 (0.05)	23	1	0
Pericarditis	105 (0.2)	43	62	0
Atrial fibrillation	1,748 (4.0)	1,719	16	13
Atrial flutter	397 (0.9)	373	20	4
Total number of ECGs	**44,080**			

tion; the QTc interval AUC was 0.91. Of the 100 manually-reviewed ECGs with QTc intervals longer than 450 ms but that were negative by concept query, 32% had a bundle branch block; 24% had various ST segment or T wave abnormalities; 24% had an arrhythmia, aberrant complexes, or a pacemaker; and 23% had myocardial ischemia or infarct. No ECGs contained comments suggesting QT prolongation. Only 4 ECGs had no significant electrocardiographic abnormalities that could not alter calculation of the QT interval.

Table 4 shows concept findings over the entire database.

Discussion

We studied the application of a concept-based, natural language processing system to identify QT prolongation within cardiologist-generated ECG reports. Commonly used cutoffs for diagnosing QT prolongation from the QTc intervals calculated by ECG machines were poor, with positive predictive values of only 6-21% when compared with the NLP-based approach. Physician review of ECGs with long QTc by calculation but not by the NLP query found 94% of these ECGs had findings that would confound automatic QTc calculation. No ECGs not identified by KMCI were identified as prolonged by the cardiologist. KMCI is a more accurate means of identifying QT prolongation than automated interval analysis. Due to the high provider override rates in most medication decision support systems, due in part to poor specificity [22], a medication decision support system for QT prolongation requires use of the cardiologist-generated impression.

A modified version of the NegEx negation algorithm performed well in detected negation within this dataset with a recall of 97.3% and a precision of 98.2%. Negation within ECGs was rare; overall only 1.9% of all concepts were marked as negated and 7.7% as possible. Thus, the probability of a concept the system identified as positive truly being positive was 0.998. The high recall and precision of negation detection in this dataset is likely due to a constrained vocabulary and the relative simplicity of the ECG impression sentences compared to prior studies in other clinical document types, which had recalls of 78-97% and precisions of 85-91%[18-20].

We have grouped terms such as “questionable”, “cannot rule out”, and “borderline” together. A more granular approach to negating terms may be more predictive of specific clinical outcomes. Also, negating phrases such as “no longer” indicate that a patient has a history of a finding as well as the absence of it now; the current algorithm only identifies the latter. Such information may help determine treatment efficacy. Finally, we used a rather simple “negation window” technique consisting of a certain number of words before or after a negation phrase. Some commas separate clauses while others represent a list of concepts. A more advanced algorithm could use a parsed sentence and the presence of prepositions or coordinating conjunctions to correctly size of the negation window.

The handling of “possible” findings, included in our QT prolongation query, would vary depending on application. For the purposes of decision support, inclusion of potential findings may help prevent adverse events. For example, one would want to avoid starting a drug known to prolong the QT interval in a patient that had a “borderline long QT.” In addition, many uncertain ECG findings require further workup. A patient with potential ischemia requires further evaluation, and one would likely discontinue cyclooxegenase-2 inhibitors in this patient. For research investigations, however, one may desire to exclude uncertain findings, as many ECGs indicating “cannot rule out” may represent benign changes.

The next step in this investigation involves building a decision support tool. Many resources list possible QT prolonging medications, such as the medication registry maintained at the University of Arizona [7]. A decision support system for QT prolongation could intercept orders for high-risk medications. By investigating the occurrences of medication orders in our retrospective database of inpatient admissions in individuals with QT prolongation, we may be able to identify potential medications interactions and new causes of QT prolongation. Some of these interactions may be indirect, such as the addition of a

potent cytochrome P450 inhibitor that raises serum concentrations of a known offending agent. Ideally, a medication intervention could not only intercept medications that prolong the QT interval but also those that significantly interact with those already prescribed.

Since this is a full-text concept index over a large dataset of ECGs, we also have the ability to support many other types of decision support and research venues. While a string-matching algorithm could potentially replicate the performance of the QT prolongation concept query, it would lack flexibility and scalability. By fully concept indexing, we can quickly assess multiple queries, enabling a broader range of research and decision support tools. In addition, the parent-child relationships between concepts in the UMLS ameliorate querying across broad concepts, such as myocardial infarction.

In this study, we used a general purpose concept-identification program with the entire UMLS. We optimized the algorithm to enhance synonymy and favor underspecified matches that match cardiology-related concepts. By processing these ECGs in bulk, KMCI is able to "learn" a corpus of frequently-occurring concepts and thus favors those concepts and their related concepts when encountering ambiguous matches. Other general purpose concept identification algorithms may not perform as well without similar optimizations.

The interpretation of our findings is limited. The performance of the negation algorithm and concept identifier may not translate to other repositories of ECG impressions; however, no specific optimizations were made that correspond to our institution. Second, while we evaluated the QT prolongation algorithm against a random set of ECGs for false negatives, we did not have access to the original ECG waveforms to reevaluate for potential false negatives due to errors in the cardiologists' reading; however, we expect that this would be unlikely to dramatically alter our results. Furthermore, the prevalence of QT prolongation in the KMCI-identified dataset (5.3%) carries more face validity than the QTc interval prevalence of 26.6%. Third, since cardiologists read all ECGs in our institution in a timely manner, decision support based on the textual interpretation of ECGs is feasible. It may not be practical at other institutions in which formal ECG impressions are not rapidly available. Fourth, while we have accurately identified concept matches and their negation status, this is not the same as asserting normality. Our algorithm tells the presence or absence of "atrial fibrillation," for instance, but cannot tell that there were no arrhythmias. These questions may be addressed by classifying concepts by type (e.g., "rhythm" or "perfusion abnormalities") and defining normal status. Finally, our exploratory list of concepts in Table 4 has not been formally assessed for false negatives and provides only a rough incidence of these findings in set of ECGs.

Conclusion

The combination of a negation tagging algorithm with an effective concept identifier allows rapid assessment of clinical syndromes such as QT prolongation, myocardial ischemia, or atrioventricular conduction disturbances. We believe this technique may enable large-scale research on drug adverse events and development of new decision support tools to improve cardiovascular medication safety.

Acknowledgements

We would like to thank Mr. Mark Arrieta for his assistance in assembling the database of ECGs. This work is supported by two National Library of Medicine grants, T15 LM007450 and R01 LM007995.

A Comparison of Supervised Classification Methods for Auditory Brainstem Response Determination

Paul McCullagh, Haiying Wang, Huiru Zheng, Gaye Lightbody and Gerry McAllister

Department of Computing and Mathematics, University of Ulster, United Kingdom

Abstract

The ABR is commonly used in the Audiology clinic to determine and quantify hearing loss. Its interpretation is subjective, dependent upon the expertise and experience of the clinical scientist. In this study we investigated the role of machine learning for pattern classification in this domain. We extracted features from the ABRs of 85 test subjects (550 waveforms) and compared four complimentary supervised classification methods: Naïve Bayes, Support Vector Machine, Multi-Layer Perceptron and KStar. The ABR dataset comprised both high level and near threshold recordings, labeled as 'response' or 'no response' by the human expert. Features were extracted from single averaged recordings to make the classification process straightforward. A best classification accuracy of 83.4% was obtained using Naïve Bayes and five relevant features extracted from time and wavelet domains. Naïve Bayes also achieved the highest specificity (86.3%). The highest sensitivity (93.1%) was obtained with Support Vector Machine-based classification models. In terms of the overall classification accuracy, four classifiers have shown the consistent, relatively high performance, indicating the relevance of selected features and the feasibility of using machine learning and statistical classification models in the analysis of ABR.

Keywords:

Auditory Brainstem Response, wavelet decomposition, feature extraction, classification, decision support

Introduction

The Auditory Brainstem Response (ABR) is evoked when a stimulus click is applied to a subject's ear to determine hearing acuity and integrity of the auditory pathways. If the stimulus is perceived, a response changes their electroencephalogram (EEG) within 10ms from stimulus onset (Figure 1). The amplitude of the ABR signal is approximately 1 µVolt -5µVolts and is hidden behind the background EEG and noise (approximately 50µVolts). The components of the ABR are swamped by the endogenous electrical activity of the brain and the determination of a response can be difficult particularly at low levels of acoustic stimulation, as hearing threshold is reached. The ABR waveform is extracted by coherent averaging which exploits the deterministic nature of the signal to enhance the waveform while suppressing the uncorrelated EEG, extraneous noise and artifact. It is necessary to average approximately 1000-2000 trials before the noise is sufficiently suppressed, with signal to noise ratio enhanced proportional to the square root of the number of trials.

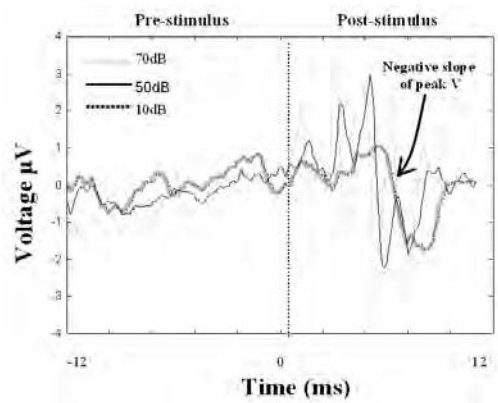

Figure 1 - ABR waveform at a 70, 50 and 10 dB Stimuli

Figure 1 shows responses for a healthy adult ranging from 70dB (normal hearing level, nHL) stimulus to threshold (10dB nHL). The characteristic shape is referred to as the Jewett waveform, comprising up to seven peaks, labeled I-VII. As the level of stimulus is reduced, the different peaks of the waveform become less defined, and their latency is increased. The shape of the waveform from the long slope at the top of peak V is the strongest part of the waveform to remain as the stimulus diminishes. When the stimulus level is set near the subject's hearing threshold the identification of wave V and its following negative slope assist with classifying the presence of the response. The shape of the ABR response will differ between subjects depending on a number of factors such as, electrode placement, filter settings, stimulus intensity, ear used, age, sex and subject's skull thickness. For this reason the range of factors need to be taken into consideration before a clinical expert can make an interpretation. In particular the expert checks the latencies of waves I, III and V and examines the morphology of the waveform. Often sub-averages based on successive recording sessions are compared for consistency and a cross-correlation may also be taken between repeat recordings to assist in classification.

The interpretation of the ABR is subjective, thus clinical experts may not always draw the same conclusion [1], particularly at auditory threshold. Artificial intelligence methods have been used to provide objective assistance in response interpretation [2]. Useful information may be extracted from the EEG recordings using features extracted from the time and frequency domains [3]. Davey [4] showed that the ratio of the power of the post over pre stimulus time domain waveforms could be used as an effective method to classify 'strong' responses with an accuracy of 98.6%. Remaining ABR waveforms, i.e. those which did not have a strong response, were passed to a second stage of analysis, whereby repeat recordings were used to derive features based on cross-correlation parameters using both the time and frequency domains. Lower accuracies ranging from 65% to 82% were achieved, dependent upon features used. The lower accuracies reflect the more difficult classification process.

Lightbody [5] used wavelet decomposition [6, 7] on the same dataset following a two-stage classification process. Power ratios of the post over pre stimulus wavelet coefficients were used to classify 'strong' responses. Those remaining were then classified using correlation features of repeated tests derived from the wavelet domain. Overall accuracy of 76.4% was obtained using a C5.0 decision tree classifier. Strong responses were classified without error. The criterion to determine a 'strong' response required a combination of time and wavelet post stimulus to pre stimulus power ratios (time domain power>2 and wavelet domain power>1.6, determined heuristically). By combining features using the Demster-Shafer method, as used in evidential reasoning [8], Davey achieved a classification accuracy of 95.6% for 'strong' responses and 85% for lower level responses [9].

In this study we compared four additional classification techniques which are in widespread use by machine learning researchers. The aim was to determine whether one of these techniques provides superior classification accuracy for the quasi-stationary ABR evoked response. Three additional statistical descriptors, namely precision, sensitivity and specificity were used to further explore the data set. The data set comprised both high and low level recordings. A secondary aim was to determine whether a single ABR recording, irrespective of level, provided sufficient information for decision support. Hence the classification process does not involve correlation parameters from repeated recordings.

Methods

The study was performed on a database of 85 test subjects, provided by the Audiology Department of the Royal Group of Hospitals in Northern Ireland. Each subject had a range of test stimulus levels applied providing a mix of good, weak and non-response waveforms, all of which were classified by a clinical expert. There were 550 waveforms in total, 396 recordings with a YES classification and 154 with a NO classification.

The data were pre-processed by band-pass filtering (100Hz-3kHz), sampled at 20kHz and then de-noised using a wavelet filter. Between 1000 and 2000 ensembles were averaged to provide one ABR waveform. Each waveform consisted of 480 data samples, half before the stimulus and half after, which related to 12ms before the stimulus and 12ms after the stimulus. The ABR waveform appears within 10ms of stimulus onset, which after band-pass filtering and sampling relates to 200 data points. A number of features were extracted from both time and wavelet domains. The Daubechies wavelet has been used to de-noise biosignals [10].

We computed a range of scaling lengths performed to 6 levels (A6: 0–156Hz, D6: 156–312Hz, D5: 312–625Hz, D4:625-1250Hz, D3:1250-2500Hz, D2:2500-5000Hz, D1:5kHz-10kHz). Levels D6, D5 and D4 showed to be of significant interest as they related to the key frequencies (200, 500 and 900Hz [11]) contained within the ABR. This is depicted in figure 2 which shows the Fast Fourier Transform (FFT) amplitude values for post-stimulus ABR waveforms at 70dB and 30dB stimulation intensities. It highlights the frequencies covered by the D6, D5 and D4 wavelet coefficients.

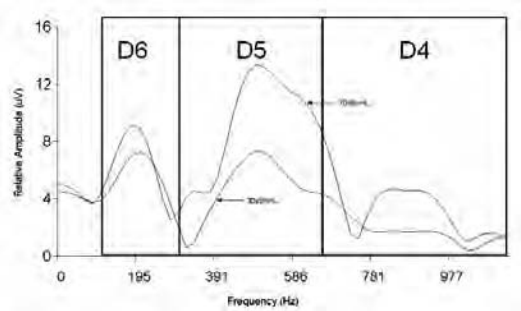

Figure 2 - FFT amplitude values for post-stimulus ABR waveforms at 70dB and 30dB stimulation intensities

Although in figure 2 the D4 coefficients seemed to show the least promising power peaks they have double the number of coefficients than the D5 range helping to reveal more feature consistency. Figure 3 illustrates the D4 component for pre and post stimulus activity for decomposition on 256 data points.

The decomposition was carried out on the full pre stimulus section and only waves I to V of the post section. Davey [4] showed that by using data from 1.5 to 9.5 ms post stimulus then the classification accuracy was improved. By focusing in on the ABR where waves I to V where most likely located removed the samples early in the waveform that may be more likely to contain artifacts and influence the classification. This same process was used for the wavelet decomposition of the post stimulus section. For both the pre and post stimulus waveforms data extension was required to extend the dataset to 256 which is the nearest dyadic number [5] so to support wavelet decomposition. Different methods to extend the data had been looked at to determine the method least likely to incur boundary issues [12].

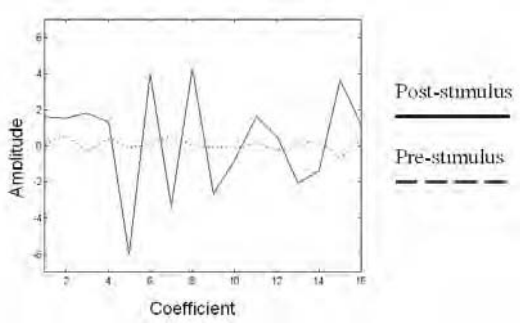

Figure 3: Extracted D4 wavelet coefficients (70dB stimulus), for pre and post-stimulus regions

An alternative partitioning of the data has been considered by performing wavelet decomposition on a smaller section of the data containing 128 data points, therefore removing the need for data extension [13]. The window of data relates to a 6.4ms section of the waveform, so the choice of window within the full post stimulus section is vitally important to ensure that the subject's response has been captured. This is crucial because as the strength of a response diminishes the peaks fade and latencies alter until peak V remains. Also, the exact position of the response differs from subject to subject. A sliding window of 128 data points was used to derive features between 1.5ms and 9.5ms of the post stimulus waveform, which was shown to be the time frame with the strongest waveforms in an ABR response [4].

Using a moving window of 128 samples from stimulus onset, the window containing the peak time domain power ratio was determined. The ABR response is expected to be at its maximum within 1.5ms and 9.5ms post stimulus. It was considered that a peak power before the 1.5ms mark could signify that the power ratio might be a result of something other than the ABR. A weighting based on the position of the peak power was used to numerically represent this doubt in the power ratio as a feature for classification. This weighting was applied to features DataAbs and DataPwr resulting in features wDataAbs and wDataPwr respectively. Whereby, DataAbs is a feature derived from the ratio of the post and pre stimulus D4 coefficients [5] (Figure 3) and DataPwr is the ratio of the post and pre stimulus time domain waveform [4]. In both cases only waves I to V in the post stimulus waveform were considered and the wavelet decomposition was performed on 256 data points resulting in 16 D4 coefficients (Figure 3).

Each 128 sample window starting from sample 35 to starting from sample 75 were independently analyzed. Power ratios were calculated labeled RNxx, where R represents the 'response' post stimulus region in the waveform and N represents the 'no response' pre stimulus region of the waveform, and 'xx' represents the starting sample for the window of data. Similar ratios for the D4, D5 and D6 wavelet coefficients were calculated for each of the 128 sample windows. Using all the D4-D6 coefficients was first considered since a 6-level decomposition of a 128 sample waveform results in a small number of coefficients (8-D4, 4-D3 and 2-D6 coefficients). Then the individual bands were considered. The last features were derived by averaging the calculated features for each of the 128 sample windows, so to capture any overall trends.

The features were used as inputs to four classification models Naïve Bayes (NB), Support Vector Machine (SVM), Multi-Layer Perceptron (MLP) and KStar. NB is a probalilistic classifier based on the Bayes rule of conditional probability. It assumes independence between features. It uses the normal distribution to model numeric attributes by calculating the mean standard deviation for each class [14]. SVM is a kernel based classifier. The basic training for SVMs involves finding a function which optimizes a bound on the generalization capability, i.e., performance on unseen data. By using the kernel trick technique, SVM can apply linear classification techniques to non-linear classification problems [15]. A MLP is a non-linear classification approach that may be trained using the back propagation algorithm. A MLP consists of multiple layers of computational units (an input layer, one or more hidden layer and one output layer). For the MLP model, the results were obtained using a model consisting of one hidden layer with six nodes when evaluating the top ten features, four nodes when evaluating the top six features and two nodes when considering the top three features (the choice of feature subsets is discussed later in the paper). Each MLP was trained for 500 epochs and the learning rate was set to 0.3. The final classification is KStar, a relatively simple instance based method. The class of a test instance is based upon the class of those training instances similar to it, using an entropy-based distance function to compute the similarity between two cases. The underlying assumption is that similar instances will have similar classes. All four classification models were implemented within the framework provided by the open-source platform Weka package [16]. This provides a collection of machine learning algorithms for data mining tasks, which may be implemented directly or called from Java code.

In the evaluation of each classifier we used ten-fold cross validation, i.e. the entire dataset is partitioned into 10 subsets of approximately equal size. Each subset in turn is used as the test set while the other subsets are combined to form a training set. The quality of each classifier was assessed by the extent to which the correct class labels have been assigned. Each classifier is assessed by three statistical measures: Precision (Pr), Sensitivity (Se), Specificity (Sp). All the features were ranked using correlation coefficient-based ranking.

Results

The top five features are illustrated in Table 1. Table 2 details accuracy, precision, sensitivity and specificity of the classifiers in separating the two classes, based on the top 5 discriminative features. (Note as this is a two-class problem, Se and Sp are reversed for Response='NO' and Response='YES').

Table 1 - Top five predictive features

Feature	Name	Description
1	wDataAbs	Wavelet power feature: D4 (weighted)
2	DataAbs	Wavelet power feature: D4
3	RN75	Power ratio: 128 samples from 75
4	RN70	Power ratio: 128 samples from 70
5	RN65	Power ratio: 128 samples from 65

Table 3 details accuracy, precision, sensitivity and specificity of the classifiers in separating the two classes, based on the top 2 discriminative features. The accuracy and precision in determining a NO response are slightly reduced, implying that most discrimination is harnessed from the relative power measure from the wavelet domain, i.e. the D4 coefficient. Time may have a small role to play in the overall morphology.

Table 2 - Prediction results for four classifiers using 10-fold cross validation with top 5 features (wDataAbs, DataAbs, RN75, RN70, and RN65)

Method	Ac (%)	Response='NO'			Response='YES'		
		Pr (%)	Se (%)	Sp (%)	Pr (%)	Se (%)	Sp (%)
NaiveBayes	83.4	93.5	82.2	86.3	66.8	86.3	82.2
SVM	81.9	83.2	93.1	54.9	76.8	54.9	93.1
MLP	81.9	87.9	86.2	71.4	68.3	71.4	86.2
Kstar	82.2	86.9	88.1	68.0	70.4	68.0	88.1

Table 3 - Prediction results for four classifiers using 10-fold cross validation with top 2 features (wDataAbs and DataAbs)

Method	Ac (%)	Response='NO'			Response='YES'		
		Pr (%)	Se (%)	Sp (%)	Pr (%)	Se (%)	Sp (%)
NaiveBayes	81.4	86.7	86.9	68.0	68.4	68.0	86.9
SVM	80.2	81.5	93.1	49.1	74.8	49.1	93.1
MLP	80.7	84.5	89.1	60.6	69.7	60.6	89.1
KStar	81.2	85.0	89.1	62.3	70.3	62.3	89.1

Discussion

The ABR test is routinely performed to detect hearing loss (Response='NO') in the Audiology clinic. Where the ratio of post-stimulus power to pre-stimulus power is high (>5), the classification decision can be made to high accuracy (98.6%). This is manifest as a clear Jewett response. Misclassification may be due to artifact attributed to stimulus, myogenic (muscle) activity, or eye blink artifact which corrupts the ABR. Such activity may be detected by an expert due to latency; stimulus artifact occurs within the first msec post-stimulus, and myogenic artifact normally occurs after wave VII. Eye blinks may be harder to eliminate as they may be more randomly distributed in the pre and post stimulus activity and hence overlap with the ABR components. The strategy is normally to remove eye blinks at source, as much as possible, by rejecting a contaminated trial.

ABR responses with a lower post-stimulus power to pre-stimulus power ratio (<5), provide a more difficult classification task, with a classification accuracy of 76.4% reported using the C5.0 decision tree classifier. This second stage classification process required the use of correlation features, from repeated trials, to assess consistency of features. In the context of decision support this would provides a complex implementation. In this research we have utilized the same data set, to assess four additional classifiers, used by data mining researchers. The classification is based only on single ABR waveforms, which provides a more difficult classification task, but is more straightforward to implement. In the context of decision support, a classifier with high accuracy and high sensitivity is required. The best overall accuracy of 83.4% was obtained for the statistically based Naïve Bayes method, using the top five features. This has a good balance between sensitivity (82.2%) and specificity (86.3%). The SVM classifier has a higher sensitivity (93.1%), but at the expense of a lower specificity (54.9%). The SVM also maintains its sensitivity as the number of features reduces to two.

In terms of mathematical complexity, KStar, an instance-based classifier, and Naive Bayes (NB), a Bayesian theorem-based model, are relatively simple classifiers, but KStar requires additional space to store training datasets. In the case where the dataset is large, using KStar could be computation-intensive. In terms of algorithm configuration, the implementation of NB is quite straightforward. It does not require any predefined parameters. MLP and SVM have more complicated parameters settings to tune. For example, MLP requires users to specify the learning rate and the number of learning epochs in advance; and SVM requires users to predefine an appropriate kernel function. NB has been proven to be one of most proficient classification algorithms in most cases. Nevertheless, given the size of datasets studied and current advanced computational resources, the differences between four classifiers in terms of computational time are not obvious in this study. Each classifier has its own advantages. For example, NB can achieve the best results in terms of specificity (86.3%). The best sensitivity was obtained by using SVM-based classification models (93.1%). Therefore, it is

hard to say which one is best in this case. Nevertheless, it is expected that a better result could be obtained by combining different classifiers. A subsidiary aim of this study was to assess the suitability of the classifiers in evoked potential analysis. However there was little difference in the overall accuracy and the choice of classifier may be more influenced by ease of implementation. A further analysis is required to assess the agreement between the classifiers, and this can be undertaken by analyzing the classification/ misclassification of single response. This study illustrates the need for further validation of the approach by applying unseen data set to the classifiers.

Conclusions

The overall classification accuracy is quite similar for the four methods, ranging from 81.9% to 83.4% with the top 5 features and 80.2% to 81.4% with the top 2 features. These accuracies exceed the C5.0 (76.4%) determined in a previous study, but may be inflated because 'strong' responses are also included in this study as we adopt classification on a single averaged trail. A valid between-study comparison would require a 2 stage classification, as used in the previous study. Currently learning parameters required for each classifier are based on a trial-and-error approach. Combining other machine learning techniques such as the genetic algorithm to automatically determine the optimal learning parameters would enhance our methodology. All the classifiers show the consistent high accuracy which indicates the relevance of selected features and the feasibility of using machine learning and statistical classification models in the analysis of ABR. Additionally the feature ranking technique used is not optimal and could be further enhanced.

Acknowledgment

The authors wish to thank Mr HG Houston, Royal Group of Hospitals for providing classification on the ABR data set.

Abstract

The problem addressed in this work is sleepiness during driving, which often leads to accidents in the streets. Experiments with sleepy drivers took place and the EEG data were analysed in terms of non-linear methods. Sample entropy and phase synchronization variations were investigated within the signal sections corresponding to "driving events", i.e. driving mistakes or loss of control, as well as to periods of drowsiness and sleepiness, as compared to the periods of normal driving. Decreased sample entropy, indicating loss of complexity, and an increased phase synchronisation have been found in the preliminary study presented. The results are encouraging towards developing an alerting system for predicting and preventing driving accidents.

Keywords:

sleep disorders, nonlinear dynamics, automobile driving

Introduction

Sleep is necessary for human beings and its gradual loss can lead from extreme short-term sleepiness to chronic sleepiness. Yet, the conditions of modern life increase stress and often lead people into sacrificing sleep despite the negative effects on health and abilities. In addition, as much as 20% of the general population suffers to some degree from sleep disorders which may cause extreme tiredness, loss of concentration and a pronounced inability to function normally, raising the risk of causing traffic and work accidents.

Sleepiness reduces reaction time, vigilance, alertness and concentration. Lack of adequate sleeps is associated with excessive fatigue, hypovigilance, stress and impairment of attention, information processing speed and decision-making quality, which are among the key causes of serious industrial accidents, including most nuclear accidents (Chernobyl, Three-mile Island) and other large scale accidents (such as the Bhopal chemical disaster) [1]. In addition, about 40% of fatal accidents on US highways are fatigue-related, whereas sleep-related accidents account annually for as many as 240,000 motor-vehicle accidents. UK statistics show that 25% of motor accidents are associated with driver fatigue [2]. According to NASA's Aviation Safety Reporting System, approximately 21% of the aviation incidents are fatigue-related.

As sensor, communication and artificial intelligence technologies are evolving, an effort is being paid to apply and combine such technologies in ambient intelligence systems for a more secure environment that detects and copes with the effects of sleepiness. An important challenge in this effort is the development of methods to define sleep/wakefulness involuntary transitions by physiological EEG measurements. Such predictions made feasible pervasively and unobtrusively can help decrease drastically the number of fatigue or sleepiness-related accidents and make work and streets a safer place. The European IST project SENSATION is involved in this field. A series of experiments concerning involuntary sleepiness have taken place, along with development of new miniaturized relevant sensors and new tools for processing the derived data in a meaningful way.

Within this scope, a sleepy driver experiment has taken place aiming at deriving new information regarding the driver's physiological status when losing driving control. In a previous work [3], frequency analysis of these experimental data lead to findings such as an increase of slowing activity and an acute increase of the alpha waves 5-10 seconds before driving events, accompanied by A rapid decrease of both Shannon and K-L entropies have been observed just before the driving events, i.e. loss of driving control.

A more extensive quantitative analysis is presented in this work, focusing on non-linear analysis. The hypothesis tested here that EEG "systemic" features, like complexity and synchronization, as calculated during incidences of sleepiness, and mainly during a driving event, decline from the ones calculated during driving without events. The detection of "patterns of sleepiness" among such features may help predict dangerous driving events.

Materials and methods

Subjects and experimental protocol

Five subjects participated in the present study. The subjects were average drivers (mean driving experience: 8.3 years), with a mean age of 26.5 years. The experiments

were performed in CERTH, Thessaloniki, Greece, from 6 June till 27 July 2005.

The subjects were asked to stay awake for at least 24 hours, and then to arrive at CERTH premises at around 22.00. Upon arrival and after passing the standard medical examination test, the subjects' level of sleepiness was estimated by using the Karolinska Sleepiness Scale (KSS) test, and their sleepiness behavior was scaled by the M.D. by using the Epworth Sleepiness test (1 = 'extremely alert', 5 = 'neither alert nor sleepy', 9 = 'extremely sleepy – fighting sleep'), resulting in two subjects with score 7 (very sleepy), two with grade 6, and one with 5 (neither sleepy nor awake).

The measurements were performed in the CERTH experiment car. The subject had to seat at the driver seat and the attached electrodes were connected to an ambulatory EEG monitoring system. EEG channels Fp1, C3, P3, O1, Fp2, C4, P4 and O2 were recorded, along with two horizontal and two vertical EOG channels for bipolar signals, two EMG channels and two ECG channels. For the data acquisition, a sampling rate of 200Hz, for each channel of the recording. The monitoring system hardware filters were adjusted to the band pass filtering option with a frequency range of 0.5 to 70Hz for EEG, with a notch filter at the 50Hz power supply component. A battery box with power supply independence of approximately 3 hours supported the monitoring system.

An experienced driving instructor was seated at the co-driver's seat, as shown in Figure 1. At the back there was a technician monitoring the functioning of the recording equipment and a medical doctor monitoring the EEG.

Figure 1 – The experimental car with the subject and the driving instructor

Every subject drove the research vehicle for a maximum of 1 hour on a motorway. In eight cases, subjects' sleepiness level during driving was very high, and the driver instructor stopped the measurements after three or more consecutive sleepiness events (unintentionally cross the lane border). The traffic on the motorway was very low, and the task was monotonous enough to stimulate hypovigilance. The driver's behavior and the sleepiness events for each subject were manually recorded. In parallel, the experimental car was equipped with the Eyelid Sensor System (ELS), i.e. a camera and appropriate commercial software capable of sensing the eyelid movements and detecting periods of drowsiness and sleepiness. In Table 1 there is an example of such a series of driving behavior annotations.

Table 1 – Example of annotations of the driver's condition and behavior

sec	sample	code	Notes
1170	234000	–1	ELS sleepy
1890	378000	–2	Theta waves in EEG
1895	379000	–3	ELS and EEG drowsy and sleepy
2575	515000	1	driver's error, wrong breaking
3185	637000	2	driver's error, serious driving event, wrong deviation from straight line, instructor's intervention
3360	672000	2	wrong deviation from straight line, instructor's intervention
3545	709000	2	instructor's intervention
3705	741000	3	end of measurement

Preprocessing

The EEG data were firstly filtered off-line by using a 3rd order Butterworth filter (band pass range: 0.5-45 Hz), and then the Infomax Independent Component Analysis (I-ICA) technique was used in order to remove eye movements and eye blinks [4]. ICA decomposition was performed on the EEG+EOG signals by using EEGLAB software [5]. Components contaminated by artifacts were rejected, and the remaining components were mixed and projected back onto the scalp channels. The analysis was performed on the artifacts-free EEG data.

Non-linear EEG analysis

A preliminary analysis took place for five subjects with various initial KSS scores. EEG channels C3, C4, P3 and P4 have been considered and analysis has taken place in time windows corresponding to 10 secs, with 25% overlap. Within each such EEG data segment the following features have been calculated:

- Sample entropy for the assessment of complexity of each channel, and

- Phase synchronization between two channels based on Hilbert Transform. Specifically C3-C4, C3-P3, C4-P4 and P3-P4 channel pairs have been considered.

The main idea behind this analysis was that both of these non-linear features can have relation to the systems dynamics and reveal changes during driver's gradual sleepiness and during incidents of driver's loss of control.

Sample entropy

A measure of the regularity of a time series is informative about the underlying complexities in the processes giving rise to it. Pincus [6] developed a regularity/complexity measure known as the Approximate Entropy (ApEn), which assigns a nonnegative number to a time series with larger values corresponding to greater apparent randomness of the process underlying the data while smaller values point to regular features in the data. Given groups of N points in a series, the approximate entropy is related to the probability that two sequences which are similar for N points remain similar at the next point.

A modification of the Approximate Entropy has been introduced as Sample Entropy[1] by Richman and Moorman [7], who claim that approximate entropy as defined by Pincus is biased. Larger Sample Entropy values indicate greater independence, less predictability, hence greater complexity in the data. This, in turn, may imply that decreased complexity or greater regularity in the time series is associated with disease or not regular function.

Considering two sequences $y_m(i)$ and $y_m(j)$ of the form $y_m(i)=[x(i), x(i+1),\ldots,x(i+(m-1))]$, then $B^m(r)$ gives the probability that the two sequences match for m points and $A^m(r)$ gives the probability of match for m+1 points and Sample Entropy is defined according to Equation 1.

$$SampEn(m,n,r) = [-\ln(\frac{A^m}{B^m})] \quad (1)$$

Phase synchronisation

Besides complexity measures, spatial features related to the dependence among EEG channels can be considered. Another approach is to consider the time-series as the output of oscillators and quantify their interaction by measuring the phase difference between these signals. In the present work, the analytic signal approach based on Hilbert transform has been adopted [8]. Hilbert transform can be defined as shown in Equation (2), where p.v. denotes the Cauchy principal value integral (which avoids the singularities at = t, and =±∞).

$$\tilde{s}(t) = \frac{1}{\pi} p.v. \int_{-\infty}^{\infty} \frac{s(\tau)}{t-\tau} d\tau \quad (2)$$

By use of Hilbert transform, the analytic $s_A(t)$ signal is defined from the initial signal s(t), as depicted in Equation (3)

$$s_A(t) = s(t) + j\tilde{s}(t) \equiv A(t)e^{j\varphi(t)} \quad (3)$$

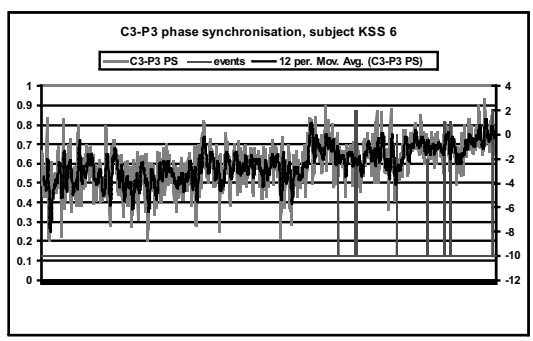
The instantaneous phase of the analytic signal is defined as shown in Equation (4)

$$\varphi(t) = \arctan\frac{\tilde{s}(t)}{s(t)} \quad (4)$$

Since instantaneous phase is available, the phase difference between channels can be calculated for each time sample. The measure of phase synchronization (PS) between two channels i and j within a time window of N samples is formulated as shown in Equation (5)

$$PS_{ij} = \frac{1}{N}\sum_{n=1}^{N} e^{j(\varphi_i(n)-\varphi_j(n))} \quad (5)$$

This is a normalized measure can vary between 0 and 1. Two channels which are synchronized for some time period will have X index close to 1 for that time window.



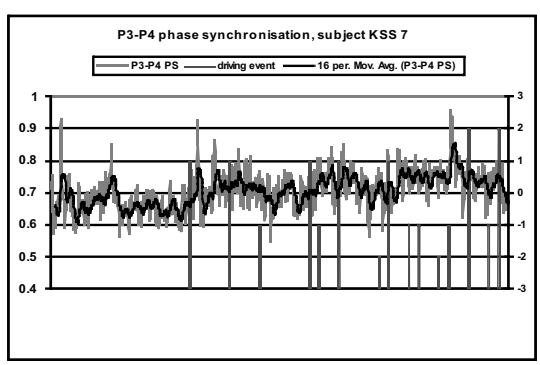


Figure 2 - Phase Synchronisation for two subjects. Synchronisation tends to increase. Events are related to periods of increased synchronization. The annotations follow the codes depicted in Table 1.

1 Matlab code for calculating Sample Entropy available at http://www.physionet.org/physiotools/sampen/

Results

The non-linear measures described above have been calculated for the five subjects with different initial sleepiness status. Since a series of such entropy and synchronization values was calculated, it was intended to seek for intra-subject differences in these features between the start and the end of the experiment, or between periods when a driving incident happened, or heavy sleepiness was reported and the rest of driving time.

Figure 2 shows the evolution of phase synchronization index and Figure 3 the evolution of Sample entropy for two subjecta, along with the annotated eventa, following the code depicted in Table 1. It can be observed that phase synchronization among the hemispheres is gradually increasing and sample entropy is decreasing, both pointing at a gradual increase of sleepiness related to loss of EEG complexity. Driving incidents seem to occur in relation to a local increase in phase synchronization and decrease in sample entropy.

In order to further evaluate possible variations of these features reflecting the subject's different condition, statistical analysis was performed. Specifically, different sets of feature data were considered, corresponding to: a) serious driving event, b) driving event, c) sleepy, d) drowsy areas, e) initial driving period without incidents and f) final driving period without incidents. The differences among some pairs of sets, i.e. serious driving event vs. initial driving period, were statistically assessed. The Wilcoxon ranksum test was applied, testing the hypothesis that populations generating two independent samples, x and y, are identical. Some results regarding these differences are depicted in Figure 4(a).

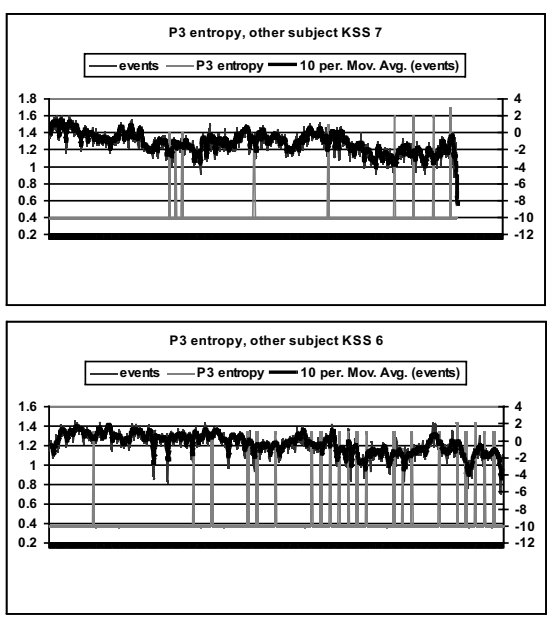

Figure 3- Sample entropy for two subjects. Events are related to periods of decreased entropy, and thus decreased complexity.

The statistical analysis showed that when there was statistical significance in the comparison, sample entropy for the aforementioned EEG channels was always lower during driving incidents than during normal driving periods. Moreover, it is interesting to notice a gradual change of the sample entropy group median values among the normal-sleepy-drowsy-event groups, as shown in Figure 4(b).

When the whole broadband signals were used in the analysis, a statistical difference in the PS feature between the normal driving period and the event period occurred for 4 out of 5 subjects. However, the expected under our hypothesis phase synchronisation elevation was evident for some cases, but not in all subjects. Specifically, an elevation clearly occurred in three out of five subjects, a decrease in two. For the sleepy/drowsy periods, the results were similar. It is possible that inter-subject variation is also related to the difference in sleepiness condition, as quantified by the KSS test. For example, the least number of statistically significant differences was found in the KSS 5 subject.

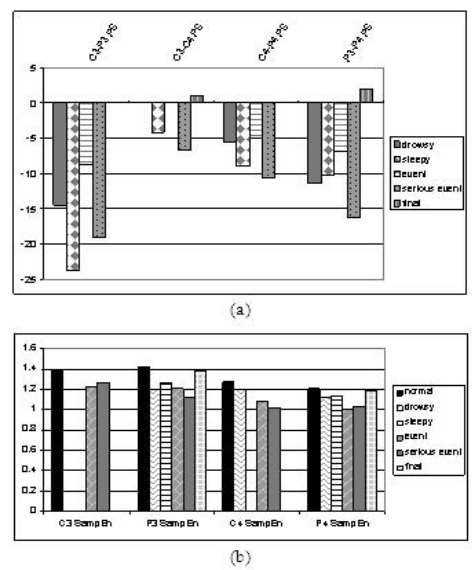

Figure 4 - a) For a subject KSS 7, the relative difference (1-value/initial_value)% between medians of the sample entropy calculated in the initial period and in the periods of various annotations. Calculations take place only when there is statistical significance. b) For another KSS 7 subject, median sample entropies for different channels and event periods than have statistical difference with the initial driving period.

When analyzing synchronization in different frequency bands (alpha and theta bands), there were some small differences, which were expected since more narrowband signals were analysed. In theta band, the statistically significant features showed a synchronisation increase for the driving event periods (4 out of 5 subjects), but that was not so persistent for the sleepy and drowsy periods. In alpha band, a phase synchronisation increase occurred for 3 out

of 5 subjects in the driving event and sleepy/drowsy periods.

It has to be noted that driver's loss of control and other annotated events do not occur momentarily, i.e. they refer to a period of time, for example not a specific second but a few seconds. Furthermore, they are manually reported by the co-driver, and their exact duration is unknown. Therefore, some inter-subject variation in the results may be explained by the variation in the definition and exact location of events. The accurate time annotation of driving events would allow the analysis or differences in pre and post event periods.

Discussion

An experiment with sleepy drivers has taken place and preliminary results of EGG data non-linear analysis have been presented. The decrease in Sample entropy and increase in Phase Synchronisation reported in this work can be regarded as measures of the system's complexity and spatial organization, complementary to the frequency band measures, traditionally applied in the sleep analysis. While these findings are somewhat macroscopic, a more extended study can seek more detailed patterns of sleepiness, to be used for prediction. A better elaboration of the driving event annotations would then be necessary. The correlation of polysomnographic signals or derived features with automatically generated driving data, as produced by the vehicle logging mechanism would be of use. This analysis can lead to an understanding of the mechanisms of alertness of drowsiness, and eventually to the prediction of dangerous driving events. The incorporation of such alertness predicting facilities in the cars can be extremely important for the driver safety. Such sensing platforms, as the one aimed by SENSATION project, must be real-time, autonomous, non-supervised, unobtrusive, and must be able to operate in non-constrained environment, able to monitor, detect and predict human physiological state in relation to alertness, fatigue and stress anytime, everywhere and for everybody.

Conclusions

A study of the intra-subject variation in sample entropy and phase synchronization in relation to driving accidents has been presented here. The non-linear measures, related to system's complexity and spatial organisation, can reveal overall system changes related to subject's vigilance, sleepiness, and hopefully predict conditions such as loss of control. The initial steady values can be used as reference, eliminating the needs for absolute thresholds. The elaboration of more detailed biosignal patterns related to the subject's driving behavior and the extended validation of our methodologies are among the future tasks of this research work.

Acknowledgments

This work has been partly supported by the IST - 2003- 507231 project SENSATION.

Abstract

The long QT syndrome (LQTS) belongs to the family of hereditary diseases and can cause life-threatening arrhythmias and leads to sudden cardiac death. Mutations on six genes are responsible for changes in the electrophysiological properties of myocardial cells that are involved in the repolarization phase. In the surface ecg this is expressed by a prolonged QT interval and genotype-specific shapes for the T-Wave. The aim of the study was to find parameters that quantify properties of the repolarization phase which can be used in addition to the established Schwartz score in the process of diagnosing LQTS. Furthermore, ecg features were evaluated for the separation of the LQT subtypes LQT1, LQT2 and LQT3. The combination of the features PtA50 and QTc yielded with 93% sensitivity and 100% specificity the best results in the field of patient identification. Despite the small dataset consisting of 14 patients that was available for the second aim, the achieved results for the morphology indices motivate further research in this field.

Keywords:

Electrocardiography, Holter, long QT-syndrome.

Introduction

The long QT syndrome (LQTS) [1] belongs to the family of hereditary diseases which can cause life-threatening arrhythmias. Most of the patients suffer from first cardiac events like syncope or cardiac arrest during childhood. Approximately 54% of them die before they reach the age of twenty if no appropriate therapy was applied.

In clinical routine the diagnosis of the LQTS is essentially based on two aspects: information from the medical history and the evaluation of the ecg. The probability for the existence of a LQTS is given by a score proposed by Schwartz et al. in 1985 and 1993 [2]. The score is expressed by a number of points that are given for a prolonged QT interval, furthermore the former presence of Torsade de pointe arrhythmias, T wave alternans, notched T waves in at least three leads in the ecg, a lowered heart rate, former syncopes, congenital deafness, the fact that other family members have a LQTS and the occurrence of sudden death in the family. In addition to the Schwartz score the molecular genetic testing becomes more and more important. But this examination method is not suitable for screening tests because of the considerable costs and time. Nevertheless this is the only way to get evidence for the existence of a LQTS.

Particularly when applied to young children the Schwartz score shows some drawbacks. Especially for young patients most points that are related to the medical history are not achievable. Furthermore the widely used frequency correction by Bazett's formula often leads to unusable values for QTc if the original heart rate is very high which is a common property for young children. So a bigger part of the possible aspects in the Schwartz score are only partially suitable for the diagnostics of affected children. Therefore additional parameters are desired to identify patients correctly.

The LQTS encompasses a disease pattern that is based on mutations on six genes (KCNQ1 → LQT1, HERG → LQT2, SCN5A → LQT3, ANK2-ß → LQT4, KCNE1 → LQT5 and KCNE2 → LQT6) which cause functional changes in selected ion channels of the myocardial cells. This leads to prolonged action potentials of the cells and is represented by a longer QT interval in the surface ecg. Furthermore the changes on the different genes are responsible for different shapes of the repolarization phase in a heart cycle as various studies have shown [3-5].

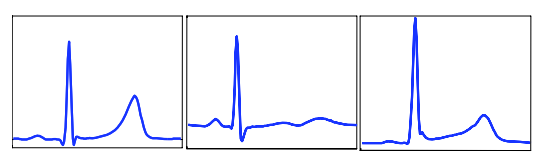

Figure 1 - Characteristic T wave shapes for LQT1 (left), LQT2 (middle) and LQT3 (right)

The drawbacks of the Schwartz score and the described T wave shape for the LQTS subtypes brings up the following

question: Do ecg parameters other than those mentioned in the Schwartz score improve the diagnostic process of LQTS? Furthermore it would be desirable that these features would also support the genotype based classification of identified patients. These two aspects might help in the diagnostic process of LQTS patients which are not identified by the Schwartz score. And additionally the time consuming process of a molecular genetic testing could be shortened if a probability for an affected gene is known.

Materials and methods

Materials and data preprocessing

24h Holter recordings from 14 genetically identified children with LQTS (age: 11,01±7,30 years; gender: f=7, m=7) and 22 healthy control persons (age: 11,31±3,75 years; gender: f=7, m=15) were used for the analysis. The group of patients is divided into three subgroups according to the genotype: LQT1 (9), LQT2 (3) and LQT3 (2).

The ecg recordings were performed using digital twelve channels recorders from Mortara Instrument Inc (Milwaukee, USA). In a first stage the recordings were processed using the Mortara Holter software H-Scribe for the identification and annotation of normal beats. All further processing was carried out using a self developed software framework for biosignal analysis [6]. An ecg viewer which is part of the framework was used to manually add missing beats that were not detected by the Holter software. Superimposed noise was removed using a highpass filter with a cut off frequency of 0,5 Hz and a lowpass filter with a cut off frequency of 50 Hz. Baseline wander was corrected using a cubic spline interpolation.

All further processing of the data except for the morphological indices was carried out using only lead V5. Due to the most distinct depiction of the repolarization phase lead V5 was chosen. Another reason is that lead V5 has the best signal to noise ratio in the considered population. To take daytime dependencies into account, three sections of the recordings were analyzed. These segments were taken from a time window in the morning starting at 8 am, from the evening starting at 6 pm and at night starting at 1 am. From these segments sequences of 10, 20, 50 and 100 consecutive normal beats are used for the analysis.

In all selected segments a self developed delineation routine to find the correct positions of Q, R, R_{Peak}, S, J, T_{Peak} and T_{End} was applied [7].

Methods

Because of the importance of the repolarization phase for the LQTS particular T wave parameters were quantified which can be assigned to the categories time interval measurements, area measurements, and morphology indices.

Time interval measurements

This category contains the features that are widely used in clinical routine. These are the intervals between prominent marker positions which were automatically inserted during the delineation process. Figure 2 demonstrates the considered intervals. All measures of this category were calculated as absolute and frequency corrected values using Bazett's formula.

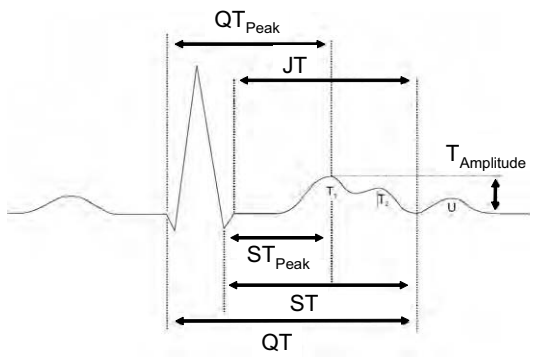

Figure 2 - Time interval measurements

Area measurements

The following area-derived parameters contain also information about the repolarization phase [8]. Table 1 summarizes the parameters in the area measurement category.

Table 1 - Area measurements

Feature	Description
A_{tot}	Total area of the repolarization phase
t_{A50}	Time interval to accumulate 50% of the area.
Pt_{A50}	Percentage of repolarization time needed to accumulate the first 50% of the area.
$t_{A25\text{-}50}$	Time interval to accumulate the mid 50% of the repolarization area from 25% to 75%.
Pt_{A25_75}	Percentage of repolarization time needed to accumulate the mid 50% of the repolarization area from 25% to 75%.
t_{A97}	Time interval to accumulate 97% of the total repolarization area
T_{amp}	Maximum amplitude of the T wave

Morphology indices

The calculated morphology indices are applied as proposed by Acar et al [9]. They characterize the spatial and temporal variations of the T wave morphology and wavefront direction differences between the depolarization and repolarization phase.

In contrast to the already described parameters the morphology indices are applied to a vector curve. It is constructed by applying a singular value decomposition on the data matrix whose rows correspond to the ecg leads I,

II, V1-V6. A summary of the morphology indices is given in table 2.

Table 2 - Morphology indices

Feature	Description
TMD	T wave morphology dispersion. Represents the variation of the morphology of the repolarization phase between different leads
TMD_{pre}	The same as TMD, but takes only the rising edge of the T wave into account
TMD_{post}	The same as TMD_{pre} with respect to the falling edge of the T wave
TCRT	Total cosine R to T. Quantifies the angle between the R- and T-wave loop
PL	Percentage of the inner area in a 2D projection that is covered by the T wave
PO	Percentage of the outer area in a 2D projection that is covered by the T wave
LD_1, LD_2	Lead dispersion 1 and 2: variation of the ecg vector during the repolarization phase

Statistical evaluation

The discriminative power of single parameters was evaluated using receiver operating characteristics (ROC) plots. Combinations of up to three parameters were used as inputs for a second order polynomial classifier. The selectivity of all results is given by values of sensitivity and specificity.

Results

As mentioned above all features were calculated for sequences of consecutive normal beats at specific times of the day. By means of this approach time dependent effects should be considered. All parameters were calculated for each single beat in the corresponding segments. To aggregate the results mean values for the parameters were calculated for the first 10, 20, 50 and 100 consecutive beats.

Patient identification

The best results for single features are given by the time interval measurements with rates of correct classified datasets of up to 97%. For two reasons these results were excluded in the further investigations. First of all the widely used Bazett formula for the frequency correction yields erroneous data sets if the heart rate is too high which is very common in young childrens. The second reason for the exclusion is the strong correlation between the parameters in this category and the fact that QTc is already part of the Schwartz score. For the remaining features those from the category of area measurements yield the best results. Table 3 lists the best features to discriminate the LQTS patients from the healthy subjects.

As table 3 shows, the best separation of the two groups is achieved in the evening segment using the parameter Pt_{A50} with values of 86% for the sensitivity and 100% for the specificity. This yields a rate of correct classifications of 93%.

Table 3 - Best single features for the identification of LQTS patients. The discriminative power is given by values for sensitivity and specificity in percentage

	10 Beats	20 Beats	50 Beats	100 Beats
Morning 09 am	t_{A50}: 86 / 91	t_{A50}: 79 / 91	t_{A50}: 79 / 91	t_{A50}: 79 / 95
Evening 06 pm	Pt_{A50}: 86 / 95	Pt_{A50}: 86 / 100	Pt_{A50}: 86 / 100	Pt_{A50}: 86 / 95
Night 01 am	Pt_{A50}: 71 / 86	t_{A25_75}: 64 / 91	t_{A25_75}: 64 / 95	Pt_{A50}: 64 / 91

The results in table 3 also indicate that the number of feature values used in the averaging process is not significant. Reliable values were achieved with a minimum number of 20 beats. The results for the morphological parameters are not suitable to separate the two groups of the study.

Combinations of two features were also evaluated. The criteria for parameters to be used in this task is given by values for the sensitivity and specificity greater than 70%. Table 4 lists the best combinations of two parameters.

Table 4 - Best feature combinations for the identification of LQTS patients. The discriminative power is given by values for sensitivity and specificity in percentage

	10 Beats	20 Beats	50 Beats	100 Beats
	2 Features			
Morning 09 am	Pt_{A50}, QTc: 86 / 100	Pt_{A50}, SPTc: 86 / 100	Pt_{A50}, QTc: 86 / 100	Pt_{A50}, QTPc: 86 / 100
Evening 06 pm	Pt_{A50}, SPTP: 86 / 100	Pt_{A50}, QTc: 86 / 100	Pt_{A50}, QTc: 93 / 100	Pt_{A50}, QTc: 93 / 100
Night 01 am	Pt_{A50}, SPTP: 93 / 91	Pt_{A50}, SPTP: 93 / 91	Pt_{A50}, SPTP: 93 / 91	t_{A25_75}, QTPc: 71 / 100

As for single features the best results for parameter combinations are achieved in the evening. A rate of 97% correctly classified datasets was achieved for the combination of Pt_{A50} and QTc.

Genotype related classification

Due to the small number of patients in the three target groups LQT1 (9 children), LQT2 (2 children) and LQT3 (3 children) a reliable classification was not possible. Nevertheless single features were evaluated with respect to their possible application for this task.

The most promising results were achieved by the area measurement t_{A50} and the morphology index TCRT. For t_{A50} the rate of overall correctly classified patients was 79% whereas TCRT yielded 77%. Despite the small sample size these result can be used as a first indicator for a genotype related classification of LQTS patients.

Discussion

The established gold standard in the diagnosis of the Long QT-syndrome is the Schwartz score as mentioned in the introduction. But especially in the diagnosis of affected young children and babies this approach often gives non-optimal results due to two limiting factors. The first one is that the frequency correction according to the Bazett formula gives erroneous values for recordings with high frequencies. Second the aspects from the previous medical history can not be taken into account as they are often not available for the young patients. Therefore the accomplished scores are often to low for the identification of affected patients. As mentioned before our work addresses these deficits by adding additional information derived from the analysis of ecg recording to the diagnostic process. These new features are not intended to replace the Schwartz score but to be used in addition especially when applied to children.

Besides of the QT interval the prolongation of the T wave can be clearly quantified by the area derived measurements as our results indicate. Approximately 68% of the whole time for the repolarization phase is needed to fill the first 50% of the covered area (Pt_{A50}) whereas healthy test persons needed only 62% of the time.

Interesting is also the fact that the used morphology indices are not suitable to describe the characteristic T wave patterns that were qualitatively described in other studies [3-5].

As our findings indicate, the area measurements and partly the morphology indices are suitable to identify LQTS patients. In combination with the traditional time interval parameters they yield the best results in the classification process. This is also in accordance with the findings of Struijk and co-workers [10] who did similar investigations on resting ecg recordings obtained from adults.

As is known, time series constructed from RR or QT intervals exhibit circadian properties. This issue was targeted during our work by the examination of three segments from the recodings covering the morning, the evening and the night. But our results indicate that circadian effects have only little influence on the discriminative power of the used features as table 3 and 5 demonstrate.

Although our findings indicate good separative properties for the time interval, area and morphology measurements they have to be interpreted with care as they are based on a relatively small dataset. The reason for this small dataset is the fact that although most of the identified patients underwent genetical testing no established mutations were found on the genes.

The results achieved so far and the aims to find ecg features that can be used in addition to the Schwartz score future investigations are needed. In this study all patients had definite results for the Schwartz score. But in cases with borderline or negative results the experience of the investigating physician is needed. So the next task is to analyze recordings from this special group of patients to validate our findings.

Conclusion

Using a collection of parameters from the categories of time interval, area and morphology measurements a good separation of patients with LQTS from healthy control persons could be achieved. The parameters were selected complementary to those mentioned in the Schwartz score and introduce new aspects in the process of diagnosing LQTS. Future work should focus especially on the question whether patients who are not identified by the Schwartz score can be recognized using the additional ecg features. Furthermore ecg parameters were evaluated that might be used to discriminate the most common LQT subtypes LQT1, LQT2 and LQT3. Although only a small dataset was available the achieved results motivate for further investigations.

Abstract

To analyze the laboratory data by data mining, user-centered universal tools have not been available in medicine. We analyzed 1,565,877 laboratory data of 771 patients with viral hepatitis in order to find the difference of the temporal changes in laboratory test data between Hepatitis B and Hepatitis C by the combination of temporal abstraction and data mining. The data for one patient is temporal for more than 5 years. After pretreatment the data was converted to abstract patterns and then selected into sets of data combination and rules to identify Hepatitis B or C by D2MS and LUPC which were originally produced by ourselves. Not only data pattern, but also temporal relations were considered as a part of the rules. In the course of evaluating the results by domain experts, even though there were not so remarkable hypotheses, visualization tools made it easier for them to understand the relations of the complicated rules.

Keywords:

databases, liver function test, hepatitis

Introduction

Data mining is beginning in medical application. Even though there are many data mining techniques to analyze the database, most of them are still experimental and in the hands of computer scientists. Medical doctors cannot use the tools for their own data analysis individually. User-centered universal tools should be applied for medical researchers to analyze their own data. In Japan we started the national project of active mining to analyze the same database of viral hepatitis and evaluate the availability and validity to implement it in medicine[1]. In this approach from the medical point of view, not only providing data, but we performed pretreatment of medical data and attended evaluation with mathematical researchers as active mining. One of the keys of laboratory data analysis in medicine is how to treat temporal data. By using temporal abstraction, we aimed to solve this problem.

The goals

One of the concrete goals of this project was to discover the differences in the temporal patterns of hepatitis B (HBV)and C (HCV) which has not been clearly defined, and, more importantly, to examine whether the methods we applied here can work well and be applied to other fields.

Materials and methods

Database

The hepatitis data is located in two databases, one is the laboratory database of the hospital, and another is the biopsy and clinical data in the department of Medical School, Chiba University. The contents are as follows:

- Basic information of patients (total 771 records)
- Results of biopsy (total 960 records)
- Information about measurements in in-hospital tests (total 459 records)
- Results of out-hospital tests (total 30,243 records) and those of in-hospital tests (total 1,565,877 records)

The data in the hospital are more than 20 years. Those patients were performed liver biopsy once at least.

Preprocessing

Our preprocessing of hepatitis data includes data cleaning, data integration, data reduction, deidentification and data transformation. We removed only redundant and not unsuitable suffix data for further processing and we eliminate noisy data in the next temporal abstraction step. For the purpose of temporal abstraction, we have to integrate original relational data tables into one data table, where each column represents laboratory examination. By combining the expert guidance and the frequencies of attributes presented from 983 examinations, we selected 15 most significant examinations. The numbers of examinations for each patient are different, and the examination periods are irregular.

Temporal abstraction

Temporal abstraction (TA) is one approach to deal with time-related data in medical research. TA methods are

those able to derive an abstract description of temporal data by

extracting their most relevant features[2] .The key idea is to transform time-stamp points by abstraction into an interval-based representation of data by extracting their most relevant features [3]. TA task can be defined as follows.

The input includes a set of time-stamped data points (events). The output includes a set of interval-based, context-specific unified values or patterns (usually qualitative) at a higher level of abstraction. TA can be generally considered in two phases: *basic* TA for abstracting time-stamped data from given episodes (which are significant intervals for the investigation purpose) and *complex* TA for investigating specific temporal relationships between episodes that can be generated from a basic TA or from other complex TAs.

Basic temporal relations

We started by a separation of two groups of tests, one with values that change rapidly in the short term such as GOT, GPT, TTT and ZTT and the other with values that change slowly in the long term such as T-CHO, CHE, ALB.

Basic temporal abstractions typically extract *states* (e.g., low, normal, high), and/or *trends* (e.g., increase, stable, decrease) from a uni-dimensional temporal sequence.

The essential ideas of our temporal abstraction methods here is to deal with long and irregular time-stamp sequences, and doing abstraction in efficient. We introduce the notion of "changes of state" to characterize the slowly changing tests, and the notions of "base state" and "peaks" to characterize the rapidly changing tests .

Temporal abstraction primitives

From observation and analysis, we defined the following temporal abstraction primitives:

1. State primitives: N (normal), L (low), VL (very low), XL (extreme low), H (high), VH (very high), XH (extreme high).
2. Trend primitives: S (stable), I (increasing), FI (fast increasing), D (decreasing), and FD (fast decreasing).
3. Peak primitives: P (peaks occurred).
4. Relations: ">" (change state to), "&" (and), "–" (and then), "/" ("X/Y" means majority of points are in state X and minority of points are in state Y).

The thresholds to distinguish the state primitives of tests are given by medical doctors, for example, those of the test GOT are 40, 100, 200, respectively. We define structures of abstraction patterns as follows:

<pattern> ::= <state primitive>

<pattern> ::= <state primitive> <relation>

<pattern> ::= <state primitive> <relation> <peak>

<pattern> ::= <state primitive> <relation> <state primitive>

Examples of abstracted patterns in a given episode are like follows:

GOT = H (all the values of GOT in one case are above the normal region as shown in the upper left in Figure 1),

"GPT = H&P" (The values of GPT in one case are always high and with peaks like lower left of Fig 1),

"I-BIL = N>L>N" (I-BIL first is normal, then changed to the low region, and finally changed to the normal region in one case like the right bottom in Fig 2) etc.

Figure 1 shows typical possible patterns (8 and undetermined) for rapidly changing tests, and *Figure 2* shows typical possible patterns (21 and undetermined) for slowly changing tests [4].

Abstraction of rapidly changing test results

From our observation and analysis, especially GPT and GOT were defined as rapidly changing attributes, which can go up in a very short period and go back to a stable" state. Thus two most representative characteristics of these tests are a "stable" base state (BS), and the position and value of peaks, where the attributes suddenly go up. Based on this, we formulated the following algorithm to find the base state and peaks of a test. Rapidly changing tests applied also to TTT and ZTT and they showed 9 patterns.

Algorithm 1 (for rapidly changing tests)

Input: A sequence of patient's values of a test with length N denoted as S_{00} = {s1, s2, …, sN} in a given episode.

Output: Base state and peaks, and an abstraction of the sequence derived from them.

Parameters: NU, HU, VHU, XHU: upper thresholds of normal, high, very high, extreme high regions of a test, a (real).

Notation:

- Mi: Set of local maximum points of S
- BS: base state of S
- PEi: set of peaks of S

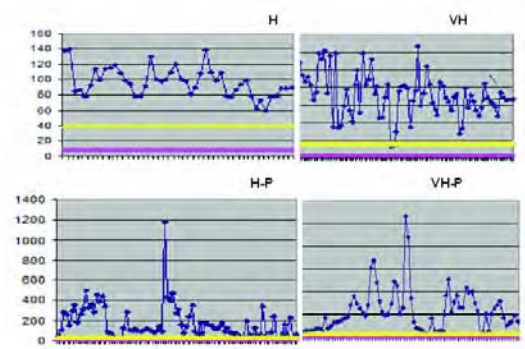

Figure 1 - rapidly changing test patterns

Abstraction of slowly changing test results

The key idea is to use the "change of state" as the main feature to characterize sequences of the tests. It can be seen that the "change of state" characterize information of both state and trend of the sequences.

From the beginning of a sequence, the first data points can be at one of the three states “N”, “H”, or “L”. It will happen that:

Either the sequence changes from one state to another state, smoothly or variably (at boundaries), or the sequence remains in its state without changing.

We provided 22patterns for slowly changing data.

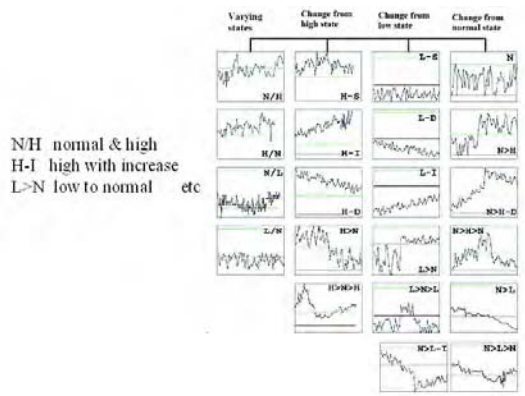

Figure 2 - Slowly changing test patterns

Temporal relationships

The temporal relations between the abstracted events of laboratory data were also treated here as phenomena and a part of the rules by comparing the period of the state. They are classified into seven relations by Allen[8].

$$Z = \frac{conf(R) - p(C)}{\sqrt{p(C)(1-p(C))/n_A}}$$

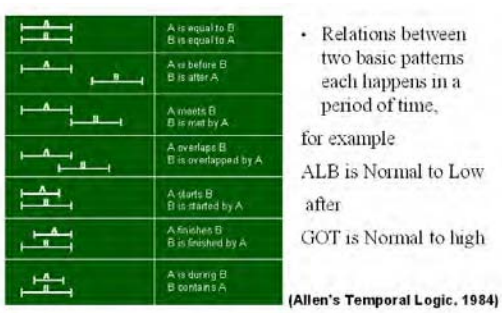

Figure 3 - Temporal relations

Complex temporal abstraction

Mining abstracted hepatitis data with system D2MS

The authors developed an interactive visualization tool in decision tree construction called D2MS (data mining for Model Selection) for supporting an effective cooperation of the user and the computer in classification. D2MS shares many features with WinViz [5] and Cviz that both use parallel coordinates. WinViz allows the user to visually examine a tabular database and to formulate query interactively and visually. Cviz is an attempt to integrate visualization into the knowledge discovery process.

D2MS facilitates the trials of various alternatives of algorithm combinations and their settings. The data mining methods in D2MS consists of programs CABRO for tree learning and LUPC for rule learning [6]. CABRO produces decision trees using R-measure and graphically represents them in particular with T2.5D tool (trees 2.5 dimension). As shown in *Figure 4*, visualization made us easily recognized the different pattern of HBV and HCV.

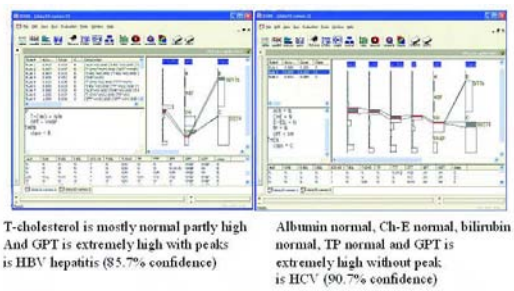

Figure 4 - Rules for HBV and HCV by D2MS

We examined statistical significance of the consequence according to the method of [7], which prunes discovered rules statistically as follows.

Assume a rule R: A C (or R: A ¬C) with confidence conf(R). If conf (R) = p(C) then R is eliminated. To test whether conf (R) = p(C), we use the following test statistic where n_A is the number of cases satisfying C

Mining abstracted hepatitis data with LUPC

LUPC is a separate-and-conquer algorithm that controls the induction process by several parameters. The parameters allow obtaining different results and this ability allows the user to play a central role in the mining process [6].

LUPC is developed to learn prediction rules from supervised data. Each rule found by LUPC is a conjunction of attribute-value pairs that may present an interesting pattern. The main features of LUPC are (1) its ability of finding rules with associate domain knowledge (such as finding rules containing or not containing specified attribute-value pairs), as well as finding rules for minority classes; (2) it is integrated with D2MS’s rule visualizer and thus supports the user in selecting the appropriate rules which result from different possible settings of parameters. The performance of LUPC depends on several parameter specified by the user: for min accuracy of rules, for min coverage of rules, for maximal number of candidate

rules in the beam search, and for maximal number of attribute-value pairs to be consider. By varying these parameters we can find different sets of rules [6]. When using the setting with default parameters of = 80%, = 3, = 200, and = 100, we found 119 rules characterizing the hepatitis B and 152 rules characterizing hepatitis C.

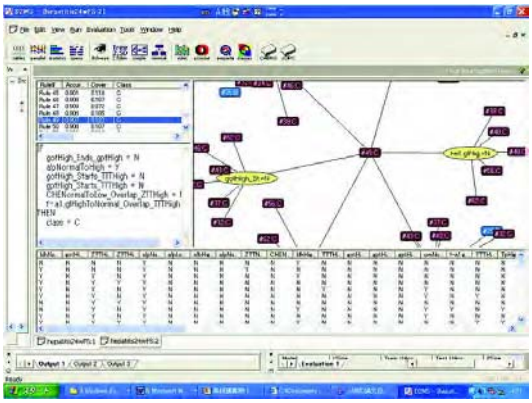

Figure 5 - LUPC Rules can be illustrated in a left figure

Evaluation

The produced rules were evaluated by three experts.

Results

By using D2MS, we discovered 33,477 rules for type B and C difference. These rules are complicated and sometimes contradictory to each other. For example, there is a rule if T-Bilirubin(Bil) is N(normal) , ZTT is N, and GOT is N with P(peak), then HBV, while there is another rule if D-Bil is N, TTT is N, GOT is N with P, then HCV, which are almost the same but the results are completely different.

After pruning by statistical aspects between HBV and HCV, there are only 27 rules (0.08%) left (*Table1*). However, these rules seemed not attractive for medical doctors even if they are statistically significant. For example, T-cholesterol is normal is HCV in 171/260 cases (66%), or GPT is high with a peak and ZTT is mostly high partly normal is HBV. They are too simple or vague and must be carefully assessed.

Different datasets were found by using LUPC with various parameters including temporal relations between laboratory tests. *Table2* presents the top five rules by LUPC from the point of coverage and confidence. From this table, especially rule3 and 5 are similar and could be merged as a rule that if TP decreasing high to normal and both ZTT and TTT is high, then it is HCV. In the evaluation of medical doctors, though most of them seemed not crucial or not useful in clinical medicine even the discovered rules covering many cases with high accuracy. However, some of the rules could be reasonable from the different clinical course of two types of hepatitis, especially when the experts checked and integrated the rules in the illustration.

Table 1 - 27 pruned rules produced by D2MS and satisfying chi-square test

No.	class	T-CHO	CHE	GOT	GPT	TTT	ZTT	D-BIL	T-BIL	I-BIL	TP	acc	ratio
1	C (95%)	N										0.66	171/260
2	C (95%)		N									0.72	183/256
3	C (95%)							N				0.73	180/248
4	C (95%)			H								0.76	89/117
5	C (95%)				H							0.76	78/103
6	C (95%)		N					N				0.82	142/173
7	C (95%)					N	H/N					0.92	11/12
8	C (95%)				H				N/H			0.93	14/15
9	B (95%)				H&P		N/H					0.92	11/12
10	B (90%)						N					0.68	83/93
11	B (90%)		H/N									0.7	14/20
12	B (90%)		N/H									0.74	23/31
13	B (90%)			N&P	H&P							0.7	16/23
14	B (90%)		N				N/H	N				0.88	7/8
15	C (90%)		N			N						0.8	67/84
16	C (90%)						H-I	N				0.95	63/66
17	C (90%)			H	XH							0.92	11/12
18	C (90%)		N	N					N			0.93	26/28
19	C (90%)										N/H	0.81	35/43
20	C (90%)					H-I				N		0.93	25/27
21	C (85%)				N&P	N						0.69	33/40
22	C (85%)		N	N								0.84	41/49
23	C (85%)		N	H								0.87	58/67
24	C (85%)					H/N				N		0.79	23/29
25	C (85%)				XH							0.72	18/25
26	C (85%)	N/L										0.8	28/35
27	C (85%)						H-D					0.83	33/40

Table 2 - Top 5 rules selected by LUPC

Rule 1(Coverage ; 4.098% confidence ; 100% coverage ; 25 cases)

creNormalToLow = Y — Creatinine decreasing from normal to low
gptHigh_Start_gotHigh = Y — and GPThigh start with GOT high
-> Class = C — is HCV

Rule 2(Coverage 3.443% confidence ;100% coverage;21 cases)
Bilirubin decreasing from normal to low before TTT elevates
is HCV

Rule 3 (Coverage 3.443% confidence ;100% coverage;21 cases)
TP decreasing high to normal and ZTT goes up to high after TTT up to high
is HCV

Rule 4 (coverage 3.279% confidence 100% coverage; 20 cases)
Creatinine decresing normal to low and bilirubin increasing normal to high
is HCV

Rule 5 (coverage 2.951% confidence 100 % coverage; 18 cases)
TP decreasing high to normal and ZTT goes up to high before TTT up to high
is HCV

In the viewer of LUPC we can see the accuracy and coverage on the upper left, rule itself in the middle and the relation of the rules and attribute value pairs in the figure to the right which can be manipulated by users (*Figure 6*). By handling it users can see the relations of each item. In this figure doctors could easily recognize if LDH is low to normal is false, then all the rules are related to HCV, while if creatinine is normal to low is false, then it is related to the rules of HBV except rule #48(center), so that the doctors could understand from a more comprehensive point. This technique was highly evaluated by medical doctors and some rules such as the top 5 were considered as meaningful.

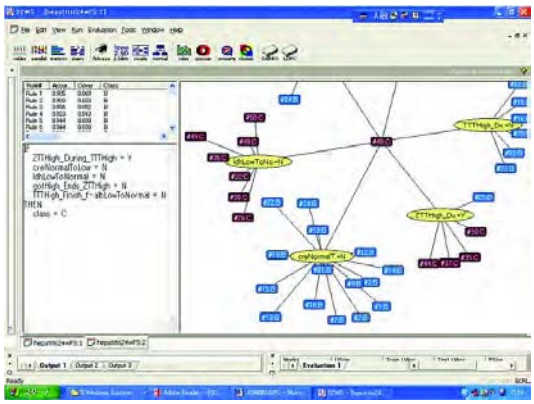

Figure 6 - LUPC makes it easier for the users to understand the relations comprehensively

Discussion

We have presented a temporal abstraction approach to data mining the temporal hepatitis data. Most doctors do not believe that they can distinguish HBV and HCV from the laboratory data change, so it might be true when we cannot obtain any new findings from this data mining. However, we in fact obtained many rules to identify HBV or HCV with statistical significance. Some of them look very simple. To confirm, we need to analyze them by stratified analysis, removing the modification of other factors such as treatment and then compare again. By LUPC, we can estimate the patient data comprehensively and expect new findings in many diseases because it is difficult for human beings to find data changes over a long period of time. some experts of liver diseases mentioned that the cases with HBV and HCV were apt to show different clinical changes, and our results would reflect these changes.

One of the major problems in rule based data mining is that there are too many rules deduced for us to evaluate. To select most important rules we introduced the chi-square test which was effective to decrease the number of rules as well as statistical reasoning. Another is by LUPC, not only selecting minority classes from large unbalanced datasets but visualization, it is not difficult to separate the important ones from many rules for medical doctors.

Other studies of data mining in medicine are mostly in the field of genomics and epidemiology and the analysis of laboratory data is quite limited. We provided the data of anti-phospholipid antibody syndrome to PKDD 1999 as model data in order to establish a new technique as well as hepatitis data.

Current medical study is deeply inclined to use a prospective way or Cohort as a scientific study design, which implies a carefully planed experiment. However, when we think of a long-term experiment lasting over 10 years, it is not realistic to study prospectively. There is a great possibility of new paradigms appearing before the study is completed. Retrospective studies are expected for these long term studies and data mining techniques will play a major role in this filed by creating high potential hypotheses.

Even though we did not discover crucial rules to show the difference of laboratory data change between HBV and HCV, we proved to show that this combination of TA and data mining with visualization is useful and effective. Furthermore, it could be applied to other fields of medicine and would be a basic model for the universal analysis of data mining for temporal data analysis in medicine.

Conclusion

The rules that show the difference of the laboratory changes in the long clinical course between the HBV and HCV could be deduced by D2MS. Pruning by statistical significance could decrease the number of rules but obtained rules were not interesting in individuals. Visualization made it easier for doctors to find the relations and led them to find reasonable results. This combination technique of temporal abstraction and data mining with visualization could be applied universally.

Abstract

Confocal Scanning Laser Tomography (CSLT) techniques capture high-quality images of the optic disc (the retinal region where the optic nerve exits the eye) that are used in the diagnosis and monitoring of glaucoma. We present a hybrid framework, combining image processing and data mining methods, to support the interpretation of CSLT optic nerve images. Our framework features (a) Zernike moment methods to derive shape information from optic disc images; (b) classification of optic disc images, based on shape information, to distinguish between healthy and glaucomatous optic discs. We apply Multi Layer Perceptrons, Support Vector Machines and Bayesian Networks for feature sub-set selection and image classification; and (c) clustering of optic disc images, based on shape information, using Self-Organizing Maps to visualize sub-types of glaucomatous optic disc damage. Our framework offers an automated and objective analysis of optic nerve images that can potentially support both diagnosis and monitoring of glaucoma.

glaucoma, data mining, feature selection, clustering, Confocal Scanning Laser Tomography, Support Vector Machines

Introduction

Glaucoma is an eye disease that is characterized by slow progressive damage to the optic disc and corresponding deterioration of the patient's vision [1]. At present, there is a gap in the understanding of the cause, the types and the natural course of glaucoma. The use of sophisticated imaging technologies, such as Confocal Scanning Laser Tomography (CSLT), capture 3-dimensional images of the optic disc that are used for diagnostic purposes [2]. However, the interpretation of CSLT images is a manual and subjective process—a trained professional has to manually define the margins of the optic nerve based on his/her training and expertise and then classify the optic nerve as normal or glaucomatous. The current process allows for misjudgments/errors in the interpretation of the CSLT image, inability to distinguish between actual and noisy images and variance in the diagnostic recommendations over a set of practitioners. The challenge, therefore, is to automate the analysis of CSLT images of the optic disc, in an objective and quantifiable manner, to support practitioners in the diagnosis and therapeutic management of glaucoma.

Researchers have analyzed optic nerve data and CSLT based images with varying results. Bowd et al [3], working with retinal tomography images applied forward and backward feature selection methods for training Multi Layer Perceptron (MLP), Support Vector Machine (SVM) and linear discriminant functions; Park et al [4] used correlation analysis and forward wrapper model to select features from optic disc data for training SVM classifiers; Swindale et al [5] used a wrapper model for feature selection to train SVM classifiers.

We have developed a data-driven Glaucoma Diagnostic Support (GDS) system that features the automatic interpretation of CSLT topography images of the optic nerve to support (a) the classification of the optic disc images to distinguish between healthy and diseased optic discs; (b) the identification of the sub-types of glaucomatous optic disc damage. This is to help further sub-classify the glaucoma patients in order to provide treatments in line with the specific morphological patterns of damage [6]; and (c) the visualization of the temporal progression of the disease for a patient over a period of time.

In this paper we present an automated approach to CSLT topography image analysis to support glaucoma diagnosis. Our multi-stage approach is a hybrid of image processing and data mining methods. In Stage 1, we apply image-processing techniques to CSLT images to derive image-defining features. In Stage 2, we apply data classification methods to the image's shape-defining features to develop classifiers that can discriminate between healthy and glaucomatous optic discs. An important task at this stage is feature selection whereby we select an optimal subset of image features that exhibit high image classification capabilities. In Stage 3, we apply data clustering techniques to the optimal subset of image-defining features in order to identify the different sub-types of glaucomatous images in the image data-set. The emergent image clusters are subsequently used to both visualize the progression of the disease and the identification of noisy optic nerve images. In Stage 4, we apply rule-induction techniques to the optimal subset of features to induce classification rules (not discussed here). These symbolic rules provide practitioners with a justification of the diagnostic recommendations by our image classifiers. For our experiments, we worked with 1257 tomography images taken at different time intervals from 136 subjects (51 healthy subjects and 85 glaucoma patients).

Methods

Figure 1 illustrates the functional design of our GDS system. We explain the methods developed for each processing stage.

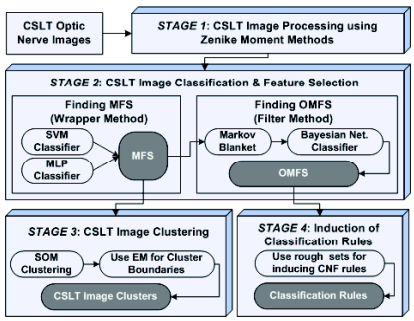

Figure 1 – Functional design of our GDS system

Stage 1: CSLT image processing

This stage involves the extraction of shape-defining features from CSLT images. These features are used to develop the image classification and clustering models. We use an image processing technique referred to as Moment Methods that describes the properties of connected regions in binary images as *Moment* features. We use Zernike moments [7] which use a set of complex polynomials to describe the image's properties by their order (n) and repetition (m) with respect to a digital image—the low order moments capture gross shape information and high order moments incrementally resolve high frequency information (representing detail) of the digital image. Two attractive features of Zernike moments for our purpose is that (a) moments can be made invariant to shifts, rotations and magnification changes; and (b) the optic nerve is centered in the image, thus avoiding the requirement for an independent segmentation stage in which the object is explicitly identified.

For each CSLT image we generated 254 Zernike moments, grouped in an incremental order ranging from 1 to 29—each group comprises a set of ordered moments. Low order moments capture fundamental geometric properties and high order moments represent detailed information of the image [7].

For efficient classification of CSLT images, it was important to select an optimal number of lower order moments. This is a non-trivial task because: (a) there is no objective measure to determine the exact number of (low order) moments needed to achieve high classification accuracy; and (b) there is no discernable relationship between the moments that can be utilized. Given these challenges, next we pursue feature subset selection in conjunction with image classification.

Stage 2: Classification of CSLT images

In the previous stage, we derived a 254 moment based representation for each CSLT image. In this stage, we pursue the classification of CSLT images based on a sub-set of low order moments. This stage therefore involves two tasks—i.e. firstly feature (sub-set) selection and secondly image classification. We have developed a two-pass image classification method that incorporates feature sub-set selection as an integral element (see Figure 1). In the first pass, MLP and SVM based wrapper models are simultaneously used to generate a *Moment Feature Subset* (MFS) consisting of low order moment features. In the second pass, we apply a Markov blanket filter method [8] based on an inferred Bayesian network to select the highly relevant moments from the MFS—i.e. the *Optimal Moment Feature Subset* (OMFS)—that offers reasonably high image classification despite using a small number of moments.

Pass I: Using MLP and SVM

In the absence of any guiding principle to determine the size of the MFS, we devised an accumulative feature subset selection strategy as follows: (a) Generate training-set by incrementally adding the next higher order moments to an existing training set. We exploited the intrinsic partitioning of the 254 moments in terms of their order ranging from 1 to 29. Therefore, feature subset1 included moments with *order2*, feature subset2 includes moments with order 2 and 3, and so on. In total 29 different training sets were generated, where each training set covered all the images based on the moment orders chosen to represent it; (b) Train both a MLP and a SVM classifier separately using the 29 training sets. In total, 29 different MLP and SVM classifiers were trained. For training the MLP and SVM, we partitioned the images so that 75% images were used for training and 25% images were used for testing. For training the SVM, based on the training data a 5-fold cross validation was performed to find the optimal hyper parameters: C and λ; and (c) Determine the classification accuracy of both classifiers, using the test images that are represented by the same number of moments as used to train the classifier.

The next step was to determine the size of the MFS and based on it to select the most efficient MLP and SVM classifier. Our objective was to select the largest possible number of moments without compromising the classification accuracy. To do so, we plotted the classification accuracy of both classifiers and then identified the highest accuracy point on the plot (i.e. with respect to n moment groups) just prior to a downward trend in the classification accuracy as a result of the inclusion of the next higher moment group. The most low order moment groups that achieved the highest classification accuracy were selected as the MFS. And, the MLP and SVM classifiers trained using the MFS were deemed as the most efficient.

A comparison of the classification accuracy trends for both the MLP and the SVM classifiers (see figure 2) shows that both classifiers exhibited a similar classification accuracy trend—i.e. they both start with a relatively high accuracy with the first moment group and then the accuracy drops with the addition of the next few moment groups. But later the accuracy starts to pick up again such that for the MLP it peaks when the feature subset constitutes the first 8 moment groups, whereas for the SVM the accuracy peaks for the first 11 moment groups. It is interesting to note that the classification accuracy with higher order moment groups is relatively low as compared to the peak achieved with just the lower order moments.

Based on classification accuracy trend for both classifiers (shown in figure 2), we determined the MFS to contain the first 11 moment groups—i.e. the first 47 moments. With 11 moment groups the SVM exhibited the highest accuracy and the MLP produced its second highest accuracy level.

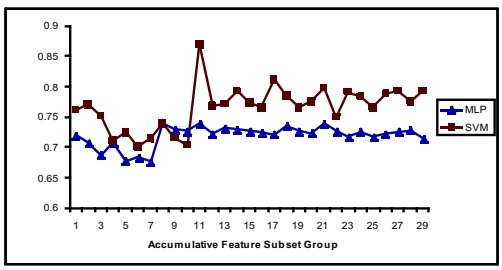

Figure 2 - Classification accuracy for both MLP and SVM

Pass II: Using Markov blanket and Bayesian network

In the second pass, we attempt to further reduce the size of the MFS in order to generate the OMFS that comprises only the highly salient moments. We use a filter model based on a Bayesian Network (BN) and the Markov blanket of the class label [8]. The choice of Markov blanket is guided by the observation that the correlation between most of the moments and their class label is weak, and the same is true for correlation between different moments. Hence, correlation based feature selection methods are not suitable here. We decided to use the Markov blanket approach as it considers every feature's probability dependence relationship during the learning procedure of the Bayesian network's structure.

In a BN where C_A is the set of children of node A, and Q_A is the set of parents of node A, the subset of nodes containing Q_A, C_A and the parents of C_A is called Markov blanket of A [8]. The Markov blanket of a specific feature is a subset of nodes in the BN; it comprises the feature's parent nodes, child nodes and all parent nodes of the child nodes. If we consider the class label node as the root node to learn a BN from data, then all nodes within the Markov blanket of the class node have probabilistic dependence relationship with it.

The steps to generate the Markov blanket were as follows: *Step 1*: We used the *K*2 algorithm to learn the BN. Initially, the 47 moments in the MFS were discretized using an entropy-based method, resulting in 29 moments to be discretized into a single value. These moments were removed from the MFS. Thus we were left with only 18 moments for training the BN. The following moments were retained: moments {1, 2, 5, 6, 7, 12, 16, 21, 23, 25, 27, 33, 36, 37, 43, 44, 45, 46}. *Step 2*: A BN was trained using the18 moments in their original order. Five-fold stratified cross validation was used to evaluate the classification accuracy (see table 2 for results). *Step 3*: The 18 moments were ordered based on the chi squared statistical test score x^2 between the moments and their class labels. The moments with the highest x^2 were: {1, 43, 16, 25, 21, 23, 6, 5, 36, 2, 27, 33, 37, 7, 46, 45, 44, 12}. A BN was learnt using the ordered moments (see table 2 for results). *Step 4*: From the BN learnt in step 3, we inferred the Markov blanket of the class label and found that only six (6) moments {1, 6, 16, 21, 37 46} were within the Markov blanket of the class label. These six moments were selected to form the OMFS. *Step 5*: In order to determine the classification capability of the selected OMFS we used them to train a BN. Next, 5-folds cross validation's classification accuracy was calculated (see table 2 for results) and it was noted that the OMFS offers quite high classification accuracy.

Stage 3: Clustering of CSLT images

In this stage we pursued the clustering of the CSLT optic nerve images, represented using the 47 moments in the MFS, to differentiate between the different subtypes of healthy and glaucomatous optic nerves. It may be noted that an important theme in glaucoma research is to develop an understanding of the large variation in the appearance of the optic nerve, both within groups of healthy subjects and in patients with glaucoma. It is therefore important, from a clinical standpoint, to recognise and differentiate between such patterns. However, the problem with the sub-classification of patterns of optic nerve damage is that it is a subjective task, giving rise to considerable levels of disagreement between trained experts. In this context, our aim was to develop an objective and automated method to characterize optic nerve images.

Our two phase clustering strategy was to: (a) partition the images into distinct clusters using Self Organizing Maps (SOM); and (b) draw clear and distinct boundaries around the clusters using the Expectation Maximization (EM) algorithm [9].

Phase A: Data clustering using SOM

We used a SOM to cluster the CSLT images based on the similarities between image shapes, where each cluster may represent a different subtype of healthy and glaucomatous optic nerves. The training of the SOM was conducted as follows: (i) we determined the topology of the SOM to be hexagonal lattice comprising 192 units that were arranged as 16 rows and 12 columns; (ii) The units were linearly initialized along the two greatest eigenvectors of the covariance matrix of the training data—i.e. images represented using the 47 moments in the MFS; (iii) The SOM was trained using a sequential training algorithm by first running a rough training phase comprising 100 epochs starting with a large neighbourhood radius of 12 that was linearly reduced to 3 with a learning rate of 0.5. This was followed by a second fine-tuning phase comprising 1000 epochs with a small initial neighbourhood radius 3 that was reduced to 1 with learning rate of 0.1. In both cases a Gaussian neighbourhood function was used and the learning rate function was set to be inversely proportional to the training epochs; (iv) Finally, we achieved a trained SOM that placed similar images into close proximity, thus leading to the image clusters. We applied principal component projection to the learnt SOM to determine its projection. This was followed by developing a U-matrix representation of the learnt SOM by spreading a colour map on the projection. Based on the visualization offered by the SOM, it was noted that the data was partitioned into discernable clusters.

Phase B: Defining the cluster boundaries

After determining broad clusters of CSLT images, in this phase we objectively determine the cluster boundaries. The processing was guided by our assumption that the dis-

tribution of the clusters within the learnt SOM is Gaussian. Therefore, we used the EM algorithm [9] as it is suitable to find distinct components in the case of Gaussian mixtures. Functionally, the EM algorithm initiates with an estimate of the number of components and their parameters. Our strategy was to maximize the likelihood of the optic nerve images into distinct clusters given the parameters and a maximum likelihood measure that indicated how well the Gaussian mixtures fit the data into clusters. We used a Bayesian Information Criterion (BIC) [9], where the best estimate (e.g., number of clusters) was chosen based on the highest BIC value.

To achieve the cluster boundaries, using the EM method with BIC, we initialized the EM using 10 random re-starts method, and then selected a parameter setting to maximize the log-likelihood of our clusters from the SOM. EM clustering was performed for different number of clusters. Table 1 shows that the maximum BIC is achieved when K = 4. Hence, we determined that given the learnt SOM there are 4 clusters—one cluster represents health images and the three clusters for sub-types of glaucomatous images—in it that best fit the data (see Table 1). To finalize the cluster boundaries for the 4 clusters, we calculated the assignment probabilities of each CSLT image to all the cluster labels, the cluster label with the highest probability value was assigned to the CSLT image. Figure 2a shows the SOM with the emergent clusters, the clusters are coded using grey scale for visualization purposes.

Table 1 – Number of clusters vs. BIC values

K	2	3	4	5	6	7	8
BIC	29100	30409	31354	30516	29125	27456	25486

Evaluation and discussion

In this section we present the evaluation results for the various methods developed for stages 2 and 3 of our GDS system.

Evaluation 1: Evaluating CSLT image classification

Table 2 presents the CSCLT image classification accuracy for the different classifiers trained in phase 2, using test images not previously seen by the classifiers. It is interesting to note that both the MLP and the SVM classifiers offered higher accuracy with the MFS as compared to the original 254 moments. This vindicates our hybrid feature sub-set selection strategy, and also confirmed the theoretical assumption that low order moments contain more shape information that is relevant for classification as compared to the information content of high order moments. In the second pass, we determined that the MFS could be further reduced to just 6 moments—i.e. the OMFS—without compromising the classification accuracy. The highest accuracy for MFS was offered by the SVM—i.e. 86.96%. The highest accuracy for the OMFS was 83.82% offered by a BN. Therefore, the compromise in classification accuracy is just 3 %, yet the gain in computational efficacy is quite significant. Note that the BN (with Markov Blanket) offers the most optimal classification results when compared with both MLP and SVM trained on the OMFS. We therefore selected the BN classifier trained with the OMFS to distinguish between healthy and glaucomatous optic nerves.

Table 2 - Classification accuracy for different classifiers

Feature Subset Size	**Classifier**	**Accuracy**
Pass I		
254 moments	MLP	72.88%
254 moments	SVM	77.50%
47 moments in MFS	MLP	74.00%
47 moments in MFS	SVM	86.96%
Pass II		
18 moments (original order)	BN	77.21%
18 moments (chi^2 order)	BN	80.88%
6 moments in OMFS	**BN**	**83.82%**
6 moments in OMFS	SVM	80.26%
6 moments in OMFS	MLP	72.84%

Evaluation 2: Examining the CSLT image clusters

Evaluation of the clustering stage involved mapping a series of optic nerve images for individual patients (i.e. test cases with explanations provided by experts) onto the SOM and noting the Compactness Factor (CF) between the activated units. The CF measures how close the images are with respect to each other in terms of the average distance between the centroid of all active units. The CF is an objective measure for evaluating the clustering goodness based on our initial observation that for a patient the series of optic nerve images are quite similar over a period of time; over time the differences are quite minute and should not lead to large variations between consecutive images. This implies that when visualizing the optic nerve images for a subject, the active units should be in close proximity and therefore yield a low CF.

Figure 2a show that the results for patient 4209643, and it maybe noted that the 7 optic nerve images, taken over a period of time, map on to a single SOM unit resulting in a compactness factor of to 0. The numeral within the active unit shows the number of images mapping on to that unit. This demonstrates the best possible clustering outcome as the learnt SOM recognizes the similarity between all the 'healthy' optic nerve images for this patient. Figures 2b shows the 11 optic nerve images of patient 112455 being mapping on to 4 neighboring SOM units within one cluster, with a compactness factor of 0.20808. This result again implies the close proximity of the images for this patient. These results are in line with the visual observations of these images by experts, who also concurred that the images for these patients are quite similar in shape.

We use the learnt SOM to visualize the disease progression for a patient over a period of time. Images taken over time for a patient were mapped onto the SOM. The pattern of the active units indicated the potential progression of the disease from one cluster to another, where each cluster may represent images of a specific glaucoma sub-type. In Figure 3a the images fall into two adjoining clusters, and the path across the clusters suggests the progression of the

disease from one sub-type to another. Figure 3b shows the progression over time.

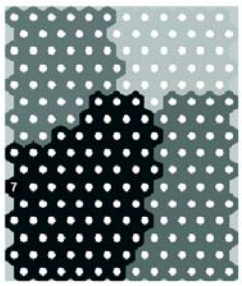

Figure 2a – SOM showing all images mapped to a unit

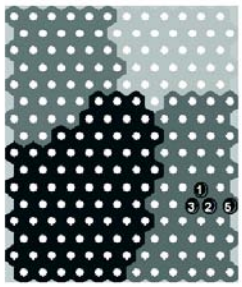

Figure 2b – SOM showing all images mapped in one cluster

Evaluation 3: Visualizing disease progression over time

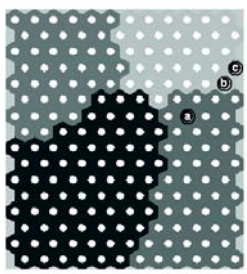

Figure 3a - SOM showing the dispersion of images over two adjoining clusters

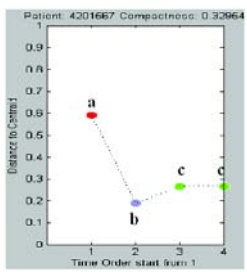

Figure 3b – The disease progression path. Note the high CF between the images

Figure 4a - SOM showing a noisy image that is distant from the other images.

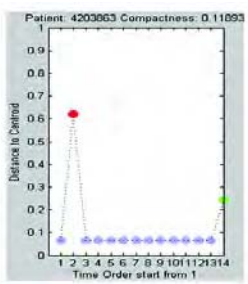

Figure 4b – The spike shows that the 2nd image is noisy, as it does not follow the pattern.

Evaluation 4: Identifying noisy CSLT images

We used the learnt SOM to identify noisy CSLT images that typically occur due to various factors related to the capture of the optic nerve image. With the knowledge that consecutive images do not manifest drastic changes, if an image is noted to be significantly dissimilar from its neighbors it can be regarded as a noisy image. At present there are no objective means to identify noisy CSLT images. Figure 4 (a-b) shows 14 images for a patient, where the 2nd image is identified as a single noisy image because it is in a different cluster, whereas the remaining images all map onto just two other units that are very close to each other.

Concluding remarks

We presented a data mining framework to objectively analyze medical images, and applied it to investigate glaucoma. The novel features of our approach are that: (a) we process CSLT images to derive shape information by using image processing techniques. This is in contrast to the traditional approach of using morphological features to analyze CSLT images; (b) we have developed a feature selection strategy that identifies the most salient image-defining features without compromising the classification accuracy; and (c) we are able to visualize the CSLT images in terms of clusters of similar images. These clusters provide an opportunity to visualize the dispersion of multiple observations for a subject, and we show how this information can help to (i) determine a potential progression of the disease due to changes in the optic disc over time; and (ii) identify noisy CSLT images. We believe that our framework takes a step towards the automated and objective analysis of optic nerve images to support glaucoma diagnostics.

Intelligent Querying and Exploration of Multiple Time-Oriented Medical Records

Denis Klimov[a], Yuval Shahar[a]

[a] *Medical Informatics Research Center, Ben Gurion University of the Negev, Israel*

Abstract

Querying and analyzing multiple time-oriented patient data is a key task during medical research, clinical trials or the assessment of the quality of therapy. In this paper, we present several aspects of the VISITORS system, which includes knowledge-based tools for graphical querying and exploration of multiple longitudinal patient records. We focus on the syntax and semantics of the knowledge-based aggregation query language for multiple time-oriented patient records, and on the graphical query-construction interface. The query language assumes an underlying computational method for deriving meaningful abstractions from single and multiple patient records, such as we had previously developed. The aggregation query language enables population querying using an expressive set of constraints. By using our underlying temporal mediator architecture, the time needed to answer typical temporal-abstraction aggregation queries on databases of 1000 to 10000 patients was reasonable.

Keywords:

intelligent visualization, temporal abstraction, multiple patients, medical informatics, Human-Computer Interfaces

Introduction: Knowledge-based exploration of multiple time-oriented records

A key task facing clinicians and medical researchers is the analysis of time-stamped, longitudinal medical records, in particular records of multiple patients. This capability is necessary to support, for example, quality assessment tasks, analysis of clinical trials, or the discovery of new clinical knowledge. Although the task of assessing patient data has been mostly solved through the increasing use of Electronic Medical Record (EMR) systems, there still remains the task of intelligent processing of multiple time-oriented patient records, including the capability for interactive exploration of the results. Standard means, such as tables, temporal statistical tools, or more advanced temporal data mining techniques, are often insufficient or can help only in particular cases.

To solve the computational aspect of this problem, we have been using the *knowledge-based temporal abstraction* (KBTA) method [1] for automated derivation of meaningful context-specific interpretations and conclusions, called *temporal abstractions*, from raw time-oriented patient data, using a domain-specific knowledge-base (KB). In general, the KBTA method is defined as follows: The input includes a set of time-stamped parameters (e.g., platelet, red blood-cell (RBC), and white blood-cell (WBC) counts) and events (e.g., bone-marrow transplantation (BMT)), which create the necessary interpretation context (e.g., the therapy protocol used). The output includes a set of interval-based, context-specific parameters at the same or a higher level of abstraction and their respective values (e.g., a period of nearly 3 months of grade 0 bone-marrow toxicity in the context of that therapy protocol).

Furthermore, the output temporal abstractions can be efficiently visualized. The KNAVE-II system, which we developed previously [2], supports the visualization and exploration of raw data and derived temporal abstractions for an individual patient or small number of patients. Evaluation of the KNAVE-II system in the oncology domain [3] has demonstrated that, by using KNAVE-II and its underlying temporal abstraction computational architecture, physicians can more quickly and more accurately answer clinical queries about patients.

However, to analyze clinical trials, or for quality assessment purposes, an aggregated view of a group of patients is more effective than exploration of each individual record separately. In addition, certain patterns can only be discovered through the analysis of multiple patients. Therefore, we have extended the KNAVE-II system into a system called VISualizatIon of Time-Oriented RecordS (VISITORS) [4] which supports the visualization of a group of time-oriented records at different levels of abstraction.

The following three important features distinguish the VISITORS framework from other exploring data tools :

1. Time-oriented data are graphically displayed and explored for both individual and multiple patients.
2. The temporal dimension is a first class citizen. It can be explored in various granularities, such as hour, day, and month. We also support a calendar timeline and a time-line relative to special events (e.g., the six months following a particular intervention).
3. The computational reasoning supports not only a view of raw time-oriented data and their statistics but also a meaningful summarization of the raw data, based on the temporal-abstraction domain ontology and the KBTA computational mechanisms. The exploration interface is also based on that ontology, which supports a semantic exploration of the data and enables navigation of semantically related raw and abstract concepts. For example, the user can explore graphically an instance of a pattern that was derived by the KBTA pattern-detection inference mechanism and view all the

abstract components and raw data from which the pattern was derived.

In this paper, we explain in detail the syntax and semantics of the VISITORS query model, which directly affect the semantics of the computational and display modules. We also introduce several of the graphic modules which we have implemented to assist users in the interactive definition of temporal aggregated queries and exploration of multiple time-oriented records. Finally, we provide results of a preliminary functional evaluation and discuss the implications of the VISITORS framework.

Methods

General architecture

The VISITORS system is an intelligent interface to a distributed architecture specific to the tasks of querying, knowledge-based visualization, and interactive exploration of time-oriented data. We assume that the necessary elements of the temporal abstraction framework (shown in Figure 1 by striped lines) are available. Figure 1 describes the overall architecture: End users (clinicians) interact with *Query Builder* of VISITORS to submit time-oriented queries regarding patients. The Temporal Abstraction Mediator, for example our previously described systems, the goal-directed IDAN Mediator [5], integrates the relevant data and knowledge from the appropriate sources, indicated by the user, to answer queries regarding raw data or to derive using a Temporal Abstraction Service the abstract time-oriented concepts. The resultant data can be visualized and explored by the user.

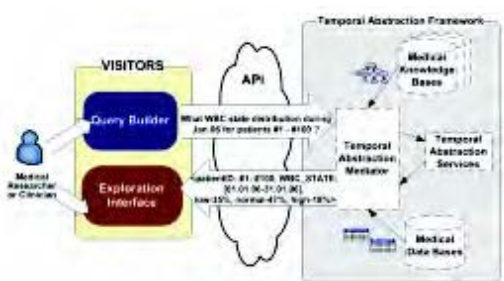

Figure 1- The distributed VISITORS architecture

Semantics of the temporal aggregation queries

We assume that the clinical time-oriented databases (DBs) have the following virtual patient record structure: the patient identification data (e.g., patient ID), name of entity (e.g., measured parameter, medications, interventions, etc.), time of laboratory test or medication and value. For example:

<John Smith,WBC,11.01.06 13:45:00,6.7*103 cells/ml>,

In our work we have designed and developed a formal query language, which is ontology-based, i.e., we use domain knowledge to formulate and display the queries. We distinguish three types of aggregated queries.

Select patients query

This query retrieves a list of patients from selected database who satisfy a set of constraints, defined by user:

GetPatients (KB, DB, <PatientsConstraints>) $\Rightarrow$ *<patients>*,

where *GetPatients* is an external procedure that queries the selected *DB*, *KB* is an appropriate knowledge base that includes the parameters definition used in *<PatientConstraints>* - a set of complex conditions defining criteria for patient selection, and *<patients>* is a resultant list of identification data of patients who satisfy the set of *<PatientConstraints>*.

The *<PatientConstraints>* aspect of the query includes the list of Boolean and temporal conditions of three types:

- **Demographic** or **non-temporal constraints** (i.e., only the last value is relevant) such as patient's ID, age, sex, physician, etc. The user can define Boolean constraints among the attribute's values (i.e., OR/AND logical operators). However, we do not recommend using complex Boolean expressions, since they make understanding why a patient was included in the output less intuitive. The logical operator NOT was omitted for a similar reason.
- **Time and value constraints** for both raw and derived concepts. To construct the query, the user can define constraints on the value of a concept, its duration, and its start/end points (See Figure 2). Both absolute (i.e., calendaric) and relative (i.e., measured from a reference event) timelines are supported. Defining pair-wise temporal relations between interrelated concepts is supported using Allen's temporal logic relation as well as relations among specific time points (i.e., start/end).

  We use the conjunction logical operator between the time and value constraints. Note that the computational functions and procedures that enabled us to derive the abstract parameters are defined in the knowledge base as part of the domain ontology. The name of the KB is specified in the query.

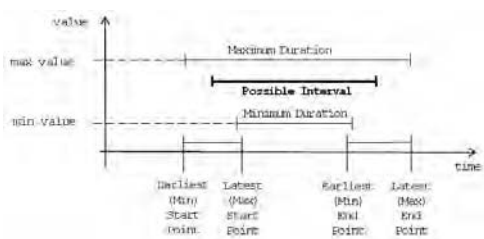

Figure 2-Time and value constraints for concept

- **Statistical Constraints** enable the user to aggregate and filter the patient's data on the basis of a specific statistical function. Using such constraints, the user is able to investigate who are the patients in the database who have specific values (or a range of values) within a given statistical range of threshold values. For example: "Select all patients whose state of WBC was derived as "low" or "very low" during more than 25% of the period Jun 1 – Oct 31 2006".

Figures 3 & 4 show an example of constructing a *Select Patients Query* with both demographic and knowledge-based constraints, whose informal definition is "Select all male patients, either younger than 20 or older than 70, whose hemoglobin (HGB) state was abstracted at least as

"moderate low" or higher, during at least seven days, starting at least two weeks after the allogenic bone marrow transplantation(BMT),and whose WBC counts were increasing during the same period." That is, either young or old patients whose bone marrows have been recovering following the BMT procedure.

The bottom part of the interfaces shown in Figures 3 and 4 displays the query that is automatically and incrementally being created from the user's graphical specification (displayed in the top part). The graphical interface used for query construction has a similar structure to the main exploration interface of the VISITORS system, which we discuss in the next section (e.g., the ontology browser is displayed on the left side; the panel display used for query definition is similar to the one used for data display, etc.). The highlighted rectangular area denotes the ranges of the time and value constraints on the patient data or abstractions relevant to the query.

Select time intervals query

Given a set of time-oriented patient data, this query returns a list of time intervals that satisfy the constraints defined by the user. In other words, the goal of this query is to find *when* a certain portion of the patients has a specific value or value in a predefined value range.

Formally, the Select Time Interval Query has the following structure:

```
GetTemporalIntervals (KB,DB,
<Constraints>, [refPoint]) ?
     relation*(<start_time, end_time>),
```

where *GetTemporalIntervals* is an external procedure that queries the selected *DB* and *KB* is an appropriate knowledge base that includes the parameters definition used in *<Constraints>*. The output *relation*(<start_time, end_time>)* is a data structure that includes a list of temporal intervals distinguished by *start_time* and *end_time* time points. The optional parameter *refPoint* requires that the output be calculated from the denoted reference point (e.g., a key clinical procedure).

<Constraints> is a logical expression without nested parentheses of the following atomic constraints related by conjunction logical operator:

```
<Concept,    min_thresh,    max_thresh,
min_value, max_value>,
```

where *Concept* is a concept name, the *min_thresh* and *max_thresh* are minimal and maximum thresholds values in percents of patients, and *min_value* and *max_value* is a range of values of the selected *Concept*.

Figure 3-Definition of a query's demographic constraints

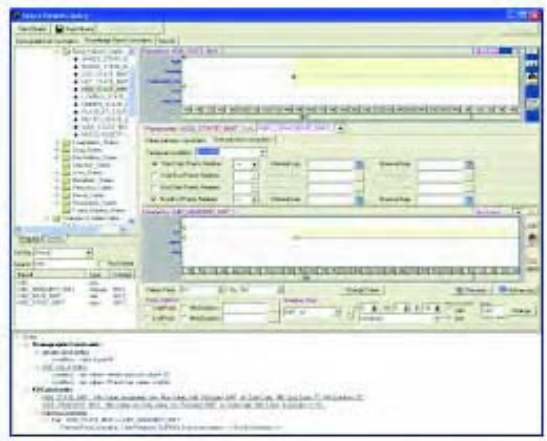

Figure 4-Definition of a query's knowledge-based constraints

For example, a typical *Select Time Interval Query* is: "Find [relative] time intervals following the BMT, during which the WBC count was increasing, and the state of the Platelet count was "normal" or higher, for more than 30% of the patients." Its formal XML based definition would be:

```
<SelectTimeIntervalsQuery>

  <Concept name="Platelet state"
min_value="normal"

           max_value="very high"

           min_theshold="30"
max_theshold="100"/>

  <Concept name="WBC
gradient"min_value="increasing"

           max_value="increasing"

           min_theshold="30"
max_theshold="100"/>

  <ReferencePoint name="BMT"
event="last"/>

</SelectTimeIntervalsQuery>
```

Get patients data query

Given a list of patients ID's and, optionally, a list of time intervals, the query retrieves the patients' raw data, or the derived temporal abstractions of one selected concept within the selected time intervals for the selected patients. The default patient list is all of the patients in the DB, and by default there are no time-interval constraints. The formal expression of the query is the following:

```
GetDataConcept(KB,DB,Concept,<patients>,[<t
ime intervals>])?
       relation*(<patient_n,
start_time_n,m, end_time_n,m,value_n,m>),
             1  n  N, 1  m  M,
```

where *GetDataConcept* is an external procedure that queries the selected DB, *KB* is an appropriate knowledge base that includes the *Concept* definition, *<patients>* is a list of patients identification data, and *<time intervals>* is an optional parameter that constrains the time of the returned

data. The output *relation*(<patient$_n$, start_time$_{n,m}$, end_time$_{n,m}$, value$_{n,m}$>)* is a data structure that includes the time-oriented data of *N* patients in <*patients*> list with *M* data records for each patient.

In contrast to the previous two queries, the *Get Patients Data Query* does not have a separate interface. This query is constructed automatically during the users' exploration of the patient's data in the main interface of VISITORS.

The main interface in VISITORS

We described previously several visualization tasks in VISITORS [4]; here we intend to explain only the main design principles of the interface.

The main interface in the VISITORS system is divided into three logical parts (See Figure 5):

The top panel (A) is used for the patients selection tasks. The user can select previously retrieved groups from the table, choose patients from a DB, input the patient ID by himself, or construct a new *Select Patients Query.*

The middle small panel (B) is used for time interval selection. The user can use the previously returned intervals, define a new interval, or construct a new *Select Time Intervals Query.* Note that both calendaric and relative timelines are supported. The main part of the interface (C) is used to explore the patients' time-oriented data. The left side includes a browser to the clinical domain ontology, retrieved on the fly from the relevant domain KB. Clicking on a concept node in the ontology tree displays the data of that concept for the selected group of patients. In this case, the user explores the data of a group of patients named *My patients* (58 patients), previously retrieved by the *Select Patients* query. The 1st panel from the top displays all of the WBC laboratory test values during March 95. The top (red) line represents the daily maximal value of the WBC count. The 2nd panel shows the daily mean value of HGB for each patient during 1995. The top (red) line and bottom (blue) line represent, respectively, the monthly maximal and minimal patient HGB values within the group. The 3rd panel displays the distribution of the WBC state-abstraction values for each month of 1995. For example, in Aug 95, 29 % of patients in the group have had a *moderately_low* value. The bottom panel displays statistical and temporal associations within the specific time period among the selected raw-data or abstracted concepts. In this case, WBC and RBC values are displayed over March 1995, and the Platelet and HGB values over 1995. Only 25 patients in the group have data in the selected time intervals. Values of all parameters for each patient are connected by lines.

The functional evaluation

We are currently performing a functional and usability evaluation of the *Query Builder* module in an oncology domain. Evaluators were asked to construct eight *Select Patients* and two *Select Time Intervals* queries at different difficulty levels (Examples of queries are showed in Table 1).

Figure 5-The main VISITORS interface

Table 1 – Examples of aggregated queries

Complexity	Examples of Queries
Select Patients Query	
Easy	Find male patients older 50 who have had during Sep 95 WBC laboratory test value less than *4000 cells/ml*.
Moderate	Find all patients who had the HGB state value in the value range "*low*" to "*normal,*", within the following time constraints: the episode of HGB starts between 3 to 4 days after allogenic BMT and its duration is at least 20 hours but no more than 60 hours.
Hard	Select male patients, whose bone-marrow toxicity grades have been decreasing for at least seven days during the period starting from 2 weeks after the allogenic BMT procedure, and whose liver toxicity grades were also decreasing during the same period.
Select Time Intervals Query	
Easy	Find time intervals when the state of WBC was considered as "normal" or higher for less than 30% of the patients
Hard	Find time intervals following the BMT procedure during which more than 20% of the patients had "*moderate*" anemia, and more than 30% of the patients had "*low*" or "*very low*" WBC counts

In all tests we used a retrospective DB of more than 1000 oncology patients after bone-marrow transplantations (BMT), who were followed for two to four years. In addition, we assessed the performance of the overall architecture when answering these queries. Results show that performance times using IDAN architecture were reasonable: several seconds for answering aggregated queries with demographic and time and value constraints for raw and abstracted parameters. We intend also to evaluate the system in the diabetic domain.

Discussion

In this paper we have presented the novel ontology-based multiple records query language, which enables users to construct a new query and retrieve a set of relevant patients or time intervals, using a broad set of constraints. Such aggregated queries, and the graphical *Query Builder* tool used to construct it, are part of the VISITORS system that enables clinicians to query, visualize and explore both raw time-oriented medical data and meaningful interpretations (including complex temporal patterns), derived from the these data, based on a domain knowledge base. The main advantage of our system is successful integration of different methods, such as information visualization and knowledge-based temporal reasoning.

In previous studies the time-oriented aspect of querying was commonly addressed by adding a temporally-oriented extension to standard SQL tools [6, 7]. However, these systems are limited in the temporal analysis by SQL capabilities. Moreover, they do not include the temporal reasoning mechanisms. In the area of visual querying, several tools have been proposed. The TimeFinder system [8] is a visual exploration and query system for exploring time-series data sets, based on a direct manipulation metaphor. Chittaro and Combi [9] provide visual representations framework of temporal intervals and relations. However, these techniques focus on query and exploration only of raw longitudinal data. Attempts to support intelligent query and retrieval are provided in the TimeLine system [10], and in knowledge-based spatial temporal query language (KSTL) [11] which support, however, only the medical imaging domain. Thus, we aimed to develop a domain-independent visual query and exploration system that enables clinicians to explore multiple longitudinal patient records, in an intelligent manner that supplies querying both raw data and their *knowledge-based meaningful interpretations*.

Analyzing Web Log Files of the Health On the Net HONmedia Search Engine to Define Typical Image Search Tasks for Image Retrieval Evaluation

Henning Müller [a], Célia Boyer [b], Arnaud Gaudinat [b], William Hersh [c], Antoine Geissbuhler [a]

[a] *Medical Informatics Service, University and Hospitals of Geneva, Geneva, Switzerland*
[b] *Health On the Net (HON), Geneva, Switzerland*
[c] *Oregon Health and Science University (OHSU), Portland, OR, USA*

Abstract

Medical institutions produce ever-increasing amount of diverse information. The digital form makes these data available for the use on more than a single patient. Images are no exception to this. However, less is known about how medical professionals search for visual medical information and how they want to use it outside of the context of a single patient. This article analyzes ten months of usage log files of the Health on the Net (HON) medical media search engine. Key words were extracted from all queries and the most frequent terms and subjects were identified. The dataset required much pre-treatment. Problems included national character sets, spelling errors and the use of terms in several languages.

The results show that media search, particularly for images, was frequently used. The most common queries were for general concepts (e.g., heart, lung). To define realistic information needs for the ImageCLEFmed challenge evaluation (Cross Language Evaluation Forum medical image retrieval), we used frequent queries that were still specific enough to at least cover two of the three axes on modality, anatomic region, and pathology. Several research groups evaluated their image retrieval algorithms based on these defined topics.

Keywords:

log files analysis, image retrieval evaluation.

Introduction

An increasing amount of medical information is being produced digitally, making it available for further processing and use, i.e., for teaching and research. Much of the produced data and experiences from past cases can be used to create tools for diagnostic decision aid. A great deal of medical information is also available on the Internet, as there are increasing requests for medical information by patients and professionals [1]. MedLinePlus is one example of a repository created to inform non-professionals, patients searching for information. Another example is Health On the Net (HON), which develops quality criteria for medical web pages and has an accreditation service for pages adhering to several quality criteria. HON also runs web search engines for medical web content aimed at patients and medical professionals with a multilingual search interface[1] [2]. Much research has been done on the searching of medical texts [3] but less on how images are used and searched for, although the amount of image data being produced is rising [4]. Many medical image databases are available within institutions, mainly for teaching, but some are also made available on the Internet. These include Casimage, HEAL (Health Education Assets Library), MedPix, and the Pathopic datasets. MIRC[2] (Medical Image Resource Center) is an initiative of the Radiological Society of North America (RSNA) to unite teaching files under a single interface. These databases contain thousands of annotated images. Unfortunately, the images are only rarely indexed in search engines such as Google as they are usually only available through the search in database fields. Another problem is that the annotation is often incomplete and information on the image modality is not always given. A search for "lung CT" with Google image search in October 2005 brought 160 results, about half of them lung CTs. The abovementioned databases alone contain several thousand lung CTs.

Outside of medicine, visual information retrieval has been an extremely active research domain for more than 15 years [5]. Studies on domain-specific user requirements have been performed, for example for journalists searching for images [6] or in the cultural heritage domain [7]. In the medical field, visual information retrieval has been proposed many times as extremely useful [8, 9]. Still, most research has a limited focus on retrieval for one particular group of images [9]. Although this might be a domain with high potential impact, teaching and research are more likely to profit first from possibilities to browse very large and diverse image collections by visual properties. In the context of ImageCLEFmed [10], a challenge evaluation for medical image retrieval, two surveys were performed among medical image users [11, 12] to find out more about typical information needs and search tasks. CLEF (Cross-Language Evaluation Forum) is a challenge evaluation for retrieval of multilingual information. ImageCLEFmed in particular evaluates the quality of retrieval from multilingual medical image retrieval available on the Internet. The

1 http://www.wrapin.org/ & http://www.hon.ch/HONselect/
2 http://mirc.rsna.org/

Selected for best paper award.

surveys include five user groups: medical professionals for diagnosis, teaching, and research as well as medical students and librarians. The goal of the work descried in this paper was to create realistic search tasks for ImageCLEFmed[3] based on information needs of web users. The analysis resulted in 30 search tasks used by participating research groups. Among the techniques used was analysis of log files, an active research domain [13], mainly to analyze web page design.

Materials and methods

Used data sets

The data used for this study were log files containing query terms of the HONmedia[4] search engine. The examined period of queries included ten months, from January 1, 2005 to October 31, 2005. This period was sufficient for a representative evaluation of search terms. Variations of search frequency or quality over the months were not part of our analysis. The original data set contained 53'970 queries. With each automatically extracted query term, the date and time of the query was stored. It was also stored whether the query was directly done via the HONmedia interface or referred to from Google towards HONmedia search. Many queries were in French, as the French-speaking medical community frequently uses the HON query engine. It was not possible to perform an automatic translation of the topics, as language detection is hard with only very few words. Other languages identified for the queries were English, German, Spanish, and Italian.

Pre-treatment of the data and evaluation techniques

The analysis of the data was done on a Linux computer using Perl to analyze the text files. The original data sets were transferred to pure text and the information on time and date of the query were discarded. Perl was used mainly to pre-treat the data. As data were extracted automatically and as robots perform queries on web interfaces there are many different formats for queries (sometimes broken), plus a variety of international character containing umlauts and accented characters sets that need to be combined.

Results

The data contained two groups of queries, queries directly asked via HON and queries forwarded via Google. These groups were treated separately. A total of 37'293 queries were directly performed via HONmedia and 16'677 were forwarded via Google.

Text normalization

First, normalization was necessary for the text to remove differences in coding of the strings, parameter options transmitted and for broken queries containing graphical symbols. We did not treat the word order in the queries. The steps were mainly based on a manual analysis of the data:

- Unify coding issues, to remove accents, Umlauts, national symbols, and any sort of non-text: –"()+–.
- Remove commands and options send by web robots or search engines.
- Remove URLs or fragments of URLs.
- Convert all characters to lower case.
- Change plural of frequent terms such as "images".
- Remove frequent terms to define the target media: image(s) (5'796), media (512), video(s) (334).

Over 100 rules for normalization and removal were defined and applied to clean the data. Even after the removal steps, it was apparent that an extremely large number of different queries remained. In total, there remained 5'365 different unique queries (of 16'677) for the Google queries and 17'643 different HON queries (of 37'293). This meant that almost half the queries were unique being asked only once, which made a systematic evaluation of the entire dataset hard. The number of words per query was small. Google queries contained an average of 2.01 words in our study and HON queries 1.50 words, after removing the words image, video and media. This resulted in 191 empty queries for Google and 150 for HON. The same number of queries contained only a single character.

Removal of unclear queries

After term normalization, it became clear that there are queries unimportant for further analysis. First, a group of queries concerned sexually explicit queries: In the Google queries, the following frequent terms were removed: xxx (334 times). For HON the following terms were removed: penis (114), vagina (108), breast (102), sex (65), clitoris (32), gynecology (24). Another group of queries implicitly contained similar ideas; for Google these were: accouchement (childbirth, 143), cesarienne (33). For HON: home childbirth (239), nurse (130), birth (69). Third, another group of queries were processed to remove those not containing a precise information need, some of them, such as the term "search," were simply placed by web robots trying to access information stored in web-accessible databases. For Google this included the following terms: medical images (508 times), HON (116), health (62), medical illustrations (32), repository (30). For HON, these terms included: search (1493), medical images (79), doctor (70), anatomy (65).

Most frequent queries and terms

After normalization and removal of queries, we analyzed the most frequent remaining terms. Table 1 shows the most frequent remaining terms forwarded from Google. This list contains very specific medical search requests, from specialists rather than patients. Most of the terms are in French, actually all of the most frequent 20. The specialized nature of the terms and the fact that they are in French can be explained with the fact that only these technical queries link towards HONmedia.

3 http://ir.ohsu.edu/image/

4 http://www.hon.ch/cgi-bin/HONmedia/

Table 1 - Most frequent terms forwarded from Google

Term	*Frequency*
Nerf sciatique	154
Kyste pilonidal	76
Leucemie aigue myeloblastique	72
Glossite exfoliatrice marginee	67
Fracture humerus	66
Grenouillette sublinguale	60
Hematome sous dural	57
Polype nez	56
Appendice xiphoide	53
Leucomalacie periventriculaire	51
Leucemie	46
Purpura rhumatoide	46
Scarlatine	44
Hematome retroplacentaire	40
Kyste thyreoglosse	39
Leucemie myelomonocytaire chronique	39
Leucoplasie	38
Apophyse odontoide	37
Hidradenite	37
Scoliose	34

Table 2 shows the most frequent terms directly queried with HONmedia. These terms are more likely to be from patients than specialists. The first 20 contain only a single word. More terms are in English than in French, actually all top 20, whereas a large number of the less frequent terms are in French. Most terms are of two groups: Terms describing an anatomic region or a disease. Only other terms found in the most frequent 20 are concerning symptoms or a treatment in the largest sense, such as *injection, bacteria and pain.*

Table 2 - Most frequent terms from the HONmedia search

Term	*Frequency*
Heart	381
Asthma	242
Brain	211
Diabetes	160
Liver	101
Cancer	98
Marfan	93
Kidney	77
Lung	69
Knee	69
Injection	67
Bacteria	64
Eye	60
Foot	58
Pain	58
Ear	58
Pancreas	57
Aids	57
Blood	55
HIV	54

Classified term occurrences important for us

This section analyzes only queries directly from HON as they correspond better to our needs concerning patient information search. We particularly note the most frequent terms for *anatomic region, pathology, imaging modality, symptom* and *treatment*, as these are axes to model search tasks along.

Table 3 - Frequent terms regarding modality

Term	*Frequency*
Ultrasound	47
Ecg/ekg	34/32
MRI	33
X-ray	21
Endoscopy	18

Table 3 shows modalities searched for. Interestingly, a commonly used modality (CT) is not mentioned often, whereas ECG, often discarded in medical image databases, is frequently used as it corresponds to the information needs.

Table 4 - Frequent terms regarding symptoms

Term	*Frequency*
Bacteria	64
Pain	58
Burns	42
Stress	37
Blood pressure	30

Table 4 shows symptoms searched for, where symptom is taken in a broad sense. Bacteria is not a symptom but might be interpreted from patients with flu-like symptoms looking for more information on a particular situation.

Table 5 - Frequent terms regarding treatments

Term	*Frequency*
Injection	67
Surgery	46
Stethoscope	36
Anesthesia	24
Vaccination	22

Table 5 lists terms concerning treatments, taken in a wide sense, as stethoscope is not a treatment.

Table 6 - Frequent terms regarding anatomic region

Term	*Frequency*
Heart	381
Brain	211
Liver	101
Kidney	77
Lung	69

In Table 6, frequent anatomic regions are listed that correspond well to the most frequent causes of death [14]. Also the search terms regarding pathology correspond well to diseases mentioned in [14]. Only Marfan is surprisingly frequent.

The 500 most frequent terms were analyzed accounting for almost half the search terms in total. Besides the identified five axes, some other terms are frequently queried, which are hard to classify: Human body (41), smoking (38), CPR (computerized patient record, 33), cardiology (26). It is hard to know what images or videos the users were searching for.

Table 7 - Frequent terms regarding pathology

Term	*Frequency*
Asthma	242
Diabetes	160
Cancer	98
Marfan	93
Aids/HIV	57/54

Constraints to define search tasks based on the results

From the most frequent concepts and the average number of query terms it becomes clear that users express fuzzy information needs and describe them with few terms. As the information in the HON queries corresponded better to our goal, we only used these. It is clear that information needs are often broad and it seems to aim at general illustrations (CPR, human body, AIDS …) than towards precise images of a particular modality and anatomic region. Illustrations also need to be taken into account as

frequent query words such as doctor, nurse, injection or bacteria show.

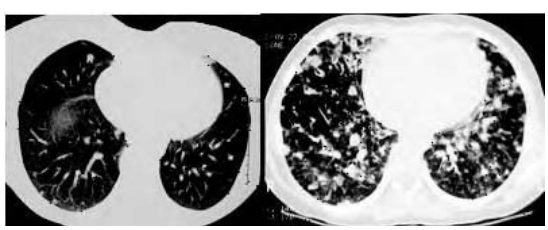
Table 8 - A collection of longer queries

Term	*Frequency*
Autonomic nervous system	16
Heart conduction system	10
Artrite reumatoide juvenil	9
Lupus vasculitis central nervous system	8
Fetal alcohol syndrome	7
Sickle cell anemia	7
Epilepsy frontal lobe	6
Respiratory distress syndrome adult	6
Spinal cord compression	6
Shoulder impingement syndrome	6

Other queries contained expected concepts but not as detailed as desired. If looking for images of the heart, all modalities, views and pathologies combined produce an extremely large number of images to be found. Such tasks are not suited to find out more about the quality of a retrieval system. For this reason, we evaluated the most frequent queries with at least three words. Table 8 lists these frequent search terms. The table shows that several terms still contain a single concept (autonomic nervous system). Most queries contain two distinct concepts, either pathology and anatomic information (epilepsy frontal lobe) or a disease and a patient group (respiratory distress syndrome adult). Still, few of these queries can be taken as query tasks for a benchmark directly.

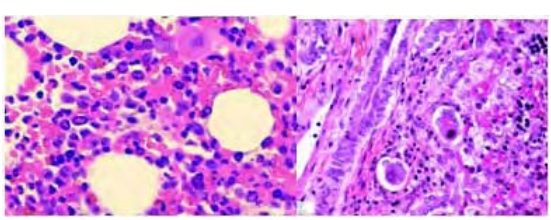
Example Query tasks of ImageCLEFmed

Finally, it was decided to use 30 real but rarer queries of the log files that cover at least two of the axes modality, anatomic region, and pathology. Example topics with example query images can be seen in Figures 1 and 2.



Show me chest CT images with nodules.
Zeige mir CT Bilder der Lunge mit Knötchen.
Montre-moi des CTs du thorax avec nodules.

Figure 1 - A visual query of ImageCLEFmed 2006



Show me microscopic images showing parvovirus infection.
Zeige mir Mikroskopien mit einer Parvovirusinfektion.
Montre-moi des images microscopiques qui montrent une infection parvovirale

Figure 2 - A semantic query for ImageCLEFmed 2006

The 30 query topics generated in this way were sent to all 40 participating research groups together with an image database. After retrieval experiments by participating groups and pooling of results, a group of physicians performed relevance judgments to compare the retrieval results of the participating retrieval systems. More about the results can be read in [15].

Discussion and conclusions

The normalization of query terms that we applied is not completely sufficient for a system that is used in several languages. A translation of the terms towards a single language or terminology would be best but with most queries being single words, this is difficult. At least 10 languages were identified. Spelling errors and abbreviations were other problems. Part of this was corrected with manual analysis but a large number of queries for the same terms could not be combined.

It can be seen that many queries for visual medical content are being performed with HONmedia search. About 52'000 queries in ten months is a large number for a small specialized search engine. Some queries are not for medical content but erotic, which is a phenomenon known by all search engines, particularly searches for images. Many queries are for illustrations of broad concepts, where the users seem to be willing to browse through a large number of varying results without a clear idea in mind and rather to illustrate an article or a presentation. Most queries are for a particular anatomic region or a certain disease. Users of the search engine do not seem to be used to supplying precise information needs concerning images. They follow the behavior of textual Internet search using broad concepts. Most image databases on the web are not well annotated and much of the information is incomplete resulting possibly in poor results.

Compared to text analysis and retrieval, medical visual information retrieval is still in its infancy. Currently, large data sets are being created and made available. Still, the applied search methods are mostly based on text, only. Techniques for visual retrieval do exist [9] and if we want to apply them in real clinical settings we need to build prototypes and make users familiar with the techniques, the possibilities and the limitations. In this sense, ImageCLEFmed is an important initiative for bringing image retrieval systems closer to routine use, through evaluating their quality. To do so, the common image databases need to be shared and realistic visual information needs have to be defined. For this, resources such as the HONmedia log files are important for us as only few medical visual search engines exist in routine use. It is also important to educate users to define their information needs more precisely using text as well as visual means and also relevance feedback.

An interesting future research topic is the analysis of query terms over short time frames. How does this behavior change with respect to events in the world (such as the bird flu)? Could the beginning of a flu outbreak be detected through keyword changes for related terms? Medical

image search on the Internet and in institutional databases has a high potential but more research is needed and particularly prototypes that can be made available to the users for testing to find out more about concrete information needs.

Abstract

The accurate quantification of disease patterns in medical images allows radiologists to track the progress of a disease. Various computer vision techniques are able to automatically detect different patterns that appear on images. However, classical pattern detection approaches do not perform satisfactorily on medical images. The problem is that texture descriptors, alone, do not capture information that is pertinent to medical images, i.e. the disease appearance and distribution. We present a method that uses knowledge of anatomy and specialised knowledge about disease appearance to improve computer-aided detection. The system has been tested on detecting honeycombing - a diffuse lung disease pattern in HRCT images of the lung. The results show that the proposed knowledge guided approach improves the accuracy of honeycombing detection. A paired t-test, shows the improvement in accuracy to be statistically significant ($p < 0.0001$).

Keywords:

lung HRCT, lung diagnosis, computer aided diagnosis, medical imaging, honeycombing detection

Introduction

Medical imaging systems are constantly improving in image quality because of increased image resolution. This results in a growing number of images that have to be inspected for diagnosis. For example, high resolution CT (HRCT) imaging protocols of the lungs can generate from 40 up to 600 images per study. These high-resolution axial images provide anatomic detail similar to that available from gross pathology specimens of lung slices [1]. Now radiologists can clearly see the alterations in lung anatomy caused by a disease process. Unfortunately, image analysis is still performed manually, which is often a difficult and time-consuming task. Consequently, there is an increasing need for computerised image analysis to facilitate image-based diagnosis.

We are developing a system for computer-aided detection of diffuse lung diseases, a large group of disorders that primarily affects the lung parenchyma. They are characterised by specific abnormal findings, mostly texture-like in appearance. Consequently, most of the automated detection algorithms, being developed to analyse CT scans are texture based. The classical approach is to use a set of image features to describe the image content and to use some classification scheme to distinguish between different patterns. For example, Uppaluri et al. [2] used twenty-two independent texture features to characterise a tissue pattern in the overlapping square regions of the lung. A Bayesian classifier was trained to discriminate between six different patterns. Uchiyama et al. [3] proposed a similar texture based technique. They trained an Artificial Neural Network with twelve features, calculated on regions with different sizes, to classify new regions. The system was trained to distinguishing between seven different patterns, which included normals and six patterns associated with diffuse lung diseases.

Our system, developed to automatically detect lung disease patterns, adopts a similar approach. However, we use a much bigger set of image attributes to describe the content of the image. We experimented with different attributes subsets and different learning schemes to improve the system's performance. The results reveal that classical pattern detection approaches do not perform satisfactorily on medical images. The problem is that texture descriptors, alone, do not capture information that is pertinent to medical images, i.e. the disease appearance and distribution. Therefore we incorporated domain knowledge of lung anatomy and lung structure to help and improve image analysis.

In this paper we focus on detecting honeycombing, an important diffuse lung disease pattern, in HRCT images of the lung. As the goal of the system is to provide radiologists with a second opinion on a lung diagnosis, it is important to achieve high accuracy. In this paper we present a new method developed to improve computer-aided detection. The method uses specialised knowledge of disease appearance in axial images. It also uses information about lung regions that are used in radiology reporting [9]. To determine if using knowledge can significantly improve the system's performance, we incorporated the knowledge-guided approach into two classification methods, one based on decision tree learning and the other using Naïve Bayes.

In the remainder of the paper, we present a computer-aided detection system using a classical pattern detection

approach. We then present the improved system and compare their performance.

Materials and methods

Lung diseases – honeycombing pattern

Honeycombing is one of the main indicators of diffuse lung diseases. It can be seen in many diseases leading to end-stage pulmonary fibrosis. Honeycombing is characterised by small, uniform (2-10mm) cystic air spaces with well-defined thick walls, (See Figure 1 left). Honeycomb cysts usually form clusters that have the characteristic appearance of "honeycombing" on HRCT images. The visual appearance of honeycombing in cross-section scans is a combination of dark and light patches. It is one of the more difficult disease patterns to detect because honeycombing can often be mistaken for other normal structures in the lung, for example, bronchi and pulmonary vessels (see Figure 1 right).

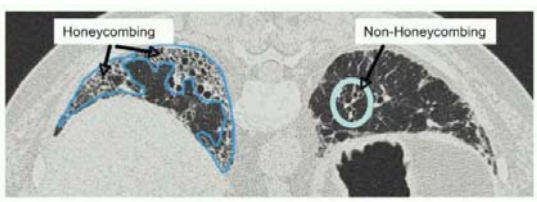

Figure 1 - Left lung- outlined region with honeycombing. Right lung –outlined example of bronchovascular structures, which has similar appearance as honeycombing.

The HRCT images

The HRCT images used for developing the computer aided disease detection system were obtained from a radiology practice. They were acquired using a SIEMENS scanner and a standard imaging protocol with 750ms exposure time. The HRCT generates volume data with spatial resolution 512x512 and 1.0mm slice thickness. For diffuse lung disease detection, radiologists usually use data with 10mm or 15mm slice gap, The data are stored in DICOM format as 16-bit greyscale images.

Describing the disease

There are specialised texts that describe how to interpret HRCT images, accompanied by illustrative examples [1]. Although this highly specialised knowledge is very useful for humans, computers cannot make direct use of it.

For computers to recognise a disease in medical images, the content of the image is represented by a set of image attributes, calculated for regions of interest (ROI) in an image. The values of these attributes depend on the characteristics of the regions. We can use these characteristic values to distinguish between normal and pathological regions as well as between different pathologies.

The method

The easiest way for a radiologist to communicate expert knowledge about how diseases appear in HRCT images is to provide examples. Using a specially developed image mark up system [4], we collected a set of images with marked and labelled regions of honeycombing and other lung diseases patterns. Figure 2 (top) shows example of an HRCT image with marked regions. Having examples of image regions with and without a disease, we were able to use supervised machine learning to generate rules for recognising different patterns in HRCT images.

The method consists of there main steps:

1. Data preparation:
   a) Image pre-processing and segmentation
   b) Feature extraction - calculating attributes for regions of interest
2. Knowledge generation - training:
   a) Feature selection – finding informative attributes for a particular disease pattern
   b) Generating rules via machine learning
3. Knowledge verification -testing the quality of the learned rules:
   a) On part of the training data
   b) On new data

Data pre-processing and segmentation

As we are interested in detecting patterns in the lungs, we first pre-process the images and segment the lungs. We have developed a lung segmentation technique based on adaptive thresholding, morphological operators and active contour snakes. Adaptive thresholding is applied to segment the darker regions in the image that represent the air-filled lung. Morphological operators are then used to include structures within the lung that have a high attenuation. Active contour snakes [5] are used to generate the lung contours (see Figure 2 bottom row).

Feature extraction

Having segmented the lung, we proceed to extract features from the image that best represent the underlying texture. A set of attributes was calculated for each pixel and it's surrounding area. We used a ROI with two window sizes, 7x7 and 15x15 pixels, to capture the characteristics of small and larger honeycombing cysts.

We calculate first and second order texture attributes and grey-level difference for each ROI [6]. The first order texture attributes measure the grey-level distribution within the ROI. Those attributes include: the mean HU[1], variance, skewness, kurtosis, energy and entropy. The second order features describe the spatial distribution of the grey-levels within these ROIs. To do this, a co-occurrence matrix is calculated that specifies the frequency of a particular grey-level occurring near another grey-level. Each pixel, with it's surrounding area, is represented by 63 attributes per window, resulting in a feature vector with 126 attributes, (63 for ROI_{7x7} and 63 for ROI_{15X15}).

1 Hounsfield unit (HU) a unit used in medical imaging (CT or MRI scanning) to describe the amount of x-ray attenuation of each "voxel" (volume element) in the three-dimensional image.

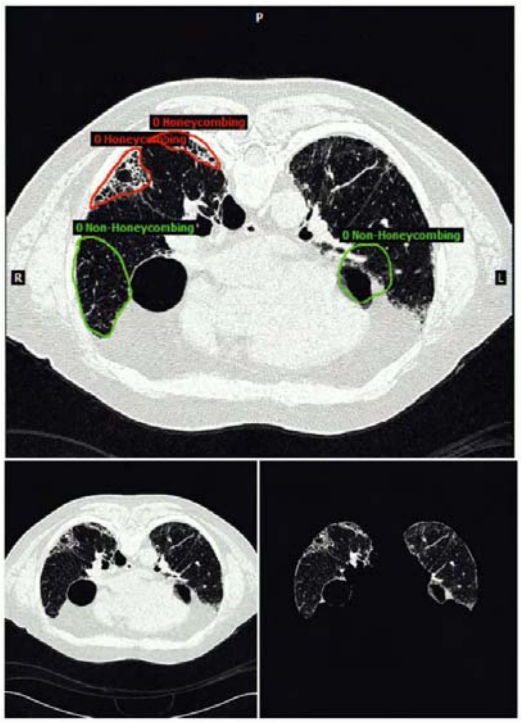

Figure 2 - Top: an image with marked and labelled regions by a radiologist showing disease patterns; bottom left: original HRCT image, bottom right: segmented lungs.

Knowledge generation process - feature selection

With a feature vector of 126 dimensions, the classifier generated would be computationally intractable. We reduce the dimensionality by selecting a subset of features that best discriminates honeycombed and non-honeycombed regions. In this study, we use Correlation-based Feature Selection (CFS) [7]. CFS selects subsets of attributes that are highly correlated with the class and that have low intercorrelation.

Generating rules via machine learning

Even with the reduced set of attributes, it is difficult to manually determine the attribute values that are characteristic for a particular pattern. We used supervised machine learning to automatically generate rules for discriminating between different patterns. In supervised learning, a set of pre-classified training examples is used to generate classification rules. In our case, the training examples consist of a set of attribute values representing a region with or without honeycombing pattern. The training set was prepared from the images with labelled regions provided by radiologists (see Figure 2 top).

We experimented with two machine learning algorithms to build the classifier: Naive Bayes and the decision tree learner, J48, both implemented in Weka data mining environment [8]. The Naive Bayes algorithm is based on a probability model. The probability of a class given a feature vector is determined using Bayes' rule:

$$P(c \mid F) = \frac{P(F \mid c)P(c)}{P(F)} \quad (1)$$

where c is the class and F is the vector of features. The class with the highest probability is assigned to the ROI. Although the Naive Bayes approach is optimal when the features are independent, in reality it still works well without this assumption. The decision tree learner generates a tree in which nodes represent tests on attributes, branches represent attribute values and leaf nodes represent classes, i.e. decisions. More informative attributes appear higher in the tree.

To train the system to detect honeycombing pattern, we used 42 images from 8 different patients that showed patterns representative of honeycombing and non-honeycombing tissue. After prepossessing and segmentation, feature extraction and selection were performed as described previously. A set of 18,407 labelled region of interest were used for training the machine learning algorithms from which 9,467 ROIs contained honeycombing and 8,940 ROIs did not. Two classifiers were built, one using Naïve Bayes and the second using decision tree induction.

Knowledge verification

Ten-fold cross validation was used to estimate the accuracy of the learned classifiers. In this validation scheme, 90% of the training data are randomly sampled for learning and 10% for testing. This is repeated 10 times and the results averaged.

The performance of the classification during training and testing was evaluated by calculating *accuracy*, *sensitivity, and specificity*. In our case *accuracy* measures the proportion of the lung that is classified correctly. *Sensitivity* determines the proportion of actual honeycombing that has been detected as honeycombing. *Specificity* measures the amount of non-honeycombing that has been classified as non-honeycombing.

Although the *accuracy*, *sensitivity* and *specificity* were comparable with the results published in the literature, we were not satisfied with the system's performance. It produced some spurious honeycombing classifications in regions where honeycombing cannot appear.

Improvements based on domain knowledge

Instead of developing post-processing methods for handling misclassifications, we decided to make use of domain knowledge about the lung structure as well as expert knowledge about the appearance of diseases. For example, Web [1] pp 91, states that "Honeycombing results in cysts …which have a peripheral predominance". This simple statement is not simple to implement. We first had to develop a model of the human lung. Next we had to develop algorithms that use anatomical knowledge to automatically generate lung regions, such as, peripheral, central, apical and basal, which are frequently used in disease reporting [9], [10]. These enabled us to determine the

Figure 3 - An HRCT image with lung regions: blue-central, red - peripheral.

lung periphery on each axial scan, which helped in desease classification.

Knowledge guided classification

In many systems (e.g. [2, 3]), all regions within the lung are classified starting from the top of the image. However, for diseases that show honeycombing, the pattern spreads from the periphery of the lung. We developed a knowledge-guided strategy for classification. This strategy uses seeded region-growing [11] and works as follows:

- The algorithm initially only classifies peripheral regions. Peripheral regions are determined using the lung regions masks. ROIs in the periphery of the lung with honeycombing are set as the "seed points" for the algorithm.
- The algorithm only classifies a region of interest if it is near other ROIs already classified as honeycombing.
- The algorithm will stop when there are no more ROIs to consider.

In summary, the knowledge guides the system to classify all ROIs that are either in the periphery of the lung or in close proximity to other ROIs classified as honeycombing.

Results

In order to test the clinical viability of the system, we evaluated the performance of our system on part of the training data and on new, previously unseen data.

Testing on the training data **-** We used ten-fold cross validation. The number of ROIs used for testing varies for each fold, as the size of the lung in each slice affects the number of ROIs that we extract. On average 9,337 ROIs were used for testing (876 ROIs for honeycombing and 8,461 ROIs for non-honeycombing). The number of ROIs containing non-honeycombing was significantly larger as most of the lung region does not show honeycombing. The average of the results are shown in Table 1.

From the results presented in Table 1, it can be seen that the knowledge-guided approach improved the accuracy of the honeycombing detection. The improvement in accuracy is attributed to a decrease in false positive classifications (sometimes by over 2%). The increase in accuracy shows that the technique is well suited for honeycombing detection. A paired t-test, shows the improvement in accuracy to be statistically significant ($p < 0.0001$).

Table 1 – Results of the two classifies: Decision Tree Induction J48 - (DTI-J48) and Naïve Bayes used with classical and knowledge-guided approach.

Classifier	DTI-J48	DTI-J48	Naïve Bayes	Naïve Bayes
	Classical	Knowledge-guided	Classical	Knowledge-guided
Accuracy	88.20%	89.70%	85.50%	87.20%
Sensitivity	96.70%	96.60%	97.50%	97.40%
Specificity	86.80%	88.60%	83.50%	85.50%

Testing on new, previously unseen data **-** Images from 8 patients, 4 patients with homecoming present and 4 patients with different disease patterns were used to test the performance of the detection system. The evaluation was performed on six images with honeycombing present and six images with out honeycombing. In total, there were 3150 regions with honeycombing and 60318 regions without honeycombing. Sensitivity of the algorithm dropped to 85%.

Conclusion

The accurate quantification of disease patterns in medical images allows radiologists to track the progress of a disease. We have developed a system that uses machine learning to automatically detect honeycombing patterns in HRCT images of the lungs. Applying a classical, texture-based, approach resulted in over detection of honeycombing. It was not possible with simple post-processing to remove the false positive regions. We improved the perfor-

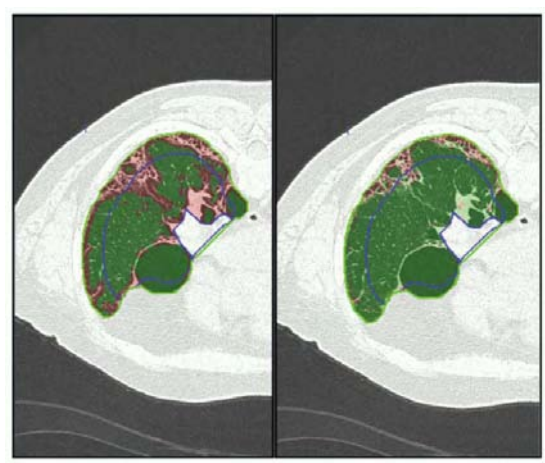

Figure 4 - Left: classification without using knowledge; right: knowledge-guided classification; red regions are classified as honeycombing; the blue line is the mask defining the periphery.

mance of the system by using knowledge-guided classification.

We tested the system with part of the training data and with new, previously unseen data. The results showed a high degree of accuracy (89.7%) and sensitivity (96.6%) on the training data. The accuracy sensitivity, however drop from 97 to 71% when testing on new data.

Experiments in building classifiers with different machine learning algorithms, Naïve Bayes and J48 decision tree learner, showed that the knowledge-guided classification performs better in both cases. The results showed that using knowledge-guided classification using the texture based Naïve Bayes classification lead to significant improvement according to pared t-test.

The domain knowledge not only improved the results of the classification, but it also improved the representation of the results. For example, a computer aided system without knowledge of lung structure reports that 5% of the fifth image contains honeycombing and that 20 % of the images 9, 10 and 11, also contain homecoming. Our system reports that 5% of honeycombing was detected in the apical area and 20% in the basal area, predominantly in the lower lobe of the left lung. Being able to use knowledge of lung anatomy in image analyses will significantly improve the detection and quantification of other lung diseases.

MR Atlas for Articular Cartilage Morphology: Potential to Detect Shape Differences

Hussain Z. Tameem[a,b], Usha S. Sinha[b]

[a] *Department of Biomedical Engineering, University of California, Los Angeles, United States*

Abstract

An atlas of the cartilage was created using free form transformation of MR images of the cartilage from 20 subjects. The deformation required to move each voxel to its corresponding location in the atlas is used to determine the differences in shape between cartilages of subjects in a population. Based on these active shape models, it is possible to localize regions of high morphological variance in population cohorts. The atlas, reported here, is based on 20 male subjects; ten symptomatic of arthritis and ten asymptomatic. The active shape models based on this atlas show regions of high morphological variance corresponding to cartilage thinning in the arthritic group. This method has the potential to differentiate between normal and arthritic population groups by detecting subtle morphological changes in articular cartilage.

Keywords:

active shape models, articular cartilage, image registration, magnetic resonance imaging, morphometry

Introduction

Osteoarthritis (OA) is a complex, progressive disease of the joint characterized by degenerative and regenerative morphological and structural changes in the articular cartilage and subchondral bone [1]. OA is a slowly progressing disease characterized clinically by pain, enlargement and deformity of the joints, and limitation of the motion. OA is the most prevalent form of arthritis and leading cause of disability and work limitation among adults resulting in enormous cost to society [2, 3]. Approximately 21 million American adults have physician diagnosed OA, [4] a diagnosis usually based on the combination of joint symptoms and radiographic changes. The prevalence of OA in a population is difficult to determine because: 1) the degree of radiological changes in symptomatic individuals varies greatly and 2) many individuals with radiographic evidence of OA have no symptoms. By age 60 nearly half of the population has radiographic evidence of OA in one or more joints, and by age 80 these findings are universal [5, 6].

Among the various sites being affected in OA, knee is the major source of reported disability and loss of function. About 40% of the adult population age 55 and older has frequent knee pain or definite x-ray evidence of knee OA [7-9]. Advanced OA accounts for majority of knee replacements surgeries among Medicare recipients. Well over 200,000 knee replacement procedures for OA are performed every year in the United States [2].

As of today, there are no reports of any disease modifying therapies for knee OA and all treatments are predominantly designed to relieve pain [10]. Approaches to prevent knee OA development, progression, or related disability are also very limited, in large part due to incomplete knowledge of potentially modifiable factors responsible for these outcomes.

In this paper, we report a method based on free-form transformation to generate an average shape atlas of the femoral cartilage and apply it to study shape differences in a population cohort. This method has potential applications in the detection of subtle shape differences in normal and diseased population groups.

Background

Previous research on cartilage morphological assessment includes its volume and thickness measurements and the impact of various factors on normal knee, such as sex, body weight and height, maturity and age, body mass index, leg length and foot size, knee bone size, bone mineral density, muscle mass, level of physical exercise and genetics [11,12,13,14]. But none of the research to date focuses on studying the shape changes in cartilage between normal and diseased state population. Also there are studies which indicate the use of mathematical frameworks such as principal component analysis (PCA) to describe general shape variations. Marcus [15] used PCA to study the variation in the skull measurements of rodent and bird species. The resulting principal modes were interpreted as size and gross shape components. Cootes et al. [16] applied the theory of PCA to build statistical shape models of organs based on manually chosen landmarks. This model provided the average positions of the points and the principal modes of variations were computed from the dataset. The ability of the method to locate structures in medical images was demonstrated in a set of experiments with echocardiograms, brain ventricle tracking and prostate segmentation. Le Briquer and Gee [17] applied PCA to analyze the displacement fields obtained from registering a reference image volume of the brain to a set of subjects, based on the elastic matching framework. The

analysis provided the inference of morphological variability within a population and was the basis for the construction of a statistical model for brain shape, which could be used as prior information to guide the registration process. Duchesne et al. proposed shape models for segmentation of the medial temporal brain structures [18].

Materials and methods

Image acquisition

We obtained the images from a pilot study conducted for the National Institute of Health OA initiative (OAI) version 0.A.1. MR images were acquired using a water-excitation double echo steady-state (DESS) imaging protocol with sagittal slices at 3.0T (Magnetom Trio®, Siemens). The imaging parameters for the sequence were: TR/TE: 16.3/4.7 ms, matrix: 384∞384, FOV: 140 mm, slice thickness: 0.7 mm, x/y resolution: 0.365/0.365 mm. Figure 1 shows a sagittal slice of the magnetic resonance image obtained using DESS sequence.

Figure 1 - MR image acquired with a DESS sequence with water-excitation at 3.0 T. The images are obtained from National Institutes of Health (NIH) OA initiative

The OAI data consists of a stratified random sample of 200 participants based on gender, sub-cohort assignment (progression and incidence) and clinic (four recruitment centers). The progression sub-cohort contains participants with symptomatic knee OA at baseline where symptoms are pain, aching or stiffness in or around the knee on most days for at least one month during the past 12 months. The incidence sub-cohort contains participants with no symptomatic knee OA at baseline, but has characteristics that place them at the risk for developing symptomatic knee OA during the study. For this study we randomly chose 20 male participants, 10 each from progression and incidence cohort group.

Atlas creation

We manually segmented the cartilage for all 20 subjects and then interpolated the raw data to a pixel resolution of 0.365x0.365x0.365 mm^3. We created the atlas in the following steps, which are illustrated in figure 2.

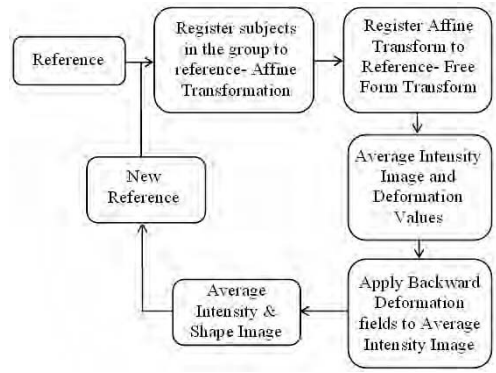

Figure 2 - Schematics of steps involved in atlas creation

Step I: We randomly chose one subject from the pool of 20 to serve as a reference to which the rest of the images were aligned utilizing the mutual information based affine transformation. Affine transform corrects for subject positioning and global size differences.

Step II: An elastic registration based on demons algorithm [19] was employed to locally map all the images in the group of subjects to the reference image using the affine transformation parameters as an initial estimation. This provides 3D deformation fields that can map the spatial locations on an individual in the group to the coordinate system of the reference. The registration algorithm computes the transformation iteratively using equation 1.

$$v_{n+1} = G_\sigma \otimes \left(v_n + G_\sigma \otimes \frac{1}{2}\left[\frac{C(T-S)\|\nabla S\|\nabla T}{(\|\nabla T\|^2 + \|\nabla S\|^2)\|\nabla S\|^2 + \|\nabla T\|^2 + 2(T-S)^2)} \nabla S \right] \right) \quad (1)$$

v_{n+1} is the correction vector field at iteration n+1, G_σ is the Gaussian filter with variance σ2, ⊗ denotes the convolution, C is the scaling factor and T and S are the target and transformed images respectively. The algorithm estimates the displacement which maps a voxel at location (*x,y,z*) in *T* to the corresponding anatomical location in *S.* The algorithm is implemented hierarchically and to preserve the morphology, deformation vector fields were computed utilizing both the forward and backward transformation.

***Step III*:** A mean intensity image with the shape of the reference image is created by averaging the globally and locally transformed images of the group.

Step IV: A mean deformation field that encodes the shape variation between the reference image and average shape of the elements in the subject group is created by averaging over 3D deformation vector fields of the individual subjects of the group.

Step V: Inverse average deformation field is applied to the average intensity image to generate and average intensity and deformation image template for the group under study.

Step VI: Steps 1-5 are iterated until no significant change in the deformation field is observed relative to the previous computation. At the end of each iteration the original reference image is replaced by the average template

Figure 3 - Accuracy of registration. Left to Right: reference, test, result of affine transform and free form deformation image. Top and bottom row showing slices at different locations. Outline from reference image shown superposed on test & aligned images.

constructed at *Step V* generating both average shape (morphometric) and intensity atlases that represent the centroid of the population data set.

Active shape models

Active shape models are used to represent the variance in cartilage shape within a given population. Active shape models based on principal component analysis of the deformation fields were created using the data from the last iteration of the atlas creation procedure [17]. With reference to the atlas creation, each iterative process results in an average atlas and deformation field d_{ir}. The deformation field, $d_{ir,}$ is the amount required to move the voxel from its original position (after global affine transformation) to the corresponding location in the atlas. Here *r* refers to the voxel, *i* represent the subjects (1-20 used to create the atlas) and *d* represents the deformation vector. The following analysis based on principal component analysis for data reduction was performed on all n voxel of the cartilage and consists of the following steps.

Step I: Calculation of the mean deformation for N subjects at each voxel as shown in equation 2 where dmean is the mean deformation at any voxel over all subjects.

$$d_{mean} = (1/N)\left(\Sigma\, d_i\right) \tag{2}$$

Step II: Computation of the deviation from the mean value as shown in equation 3

$$\Delta d_i = d_i - d_{mean} \tag{3}$$

Step III: Calculation of n∞n covariance matrix, C, to find the basis for the space as shown in equation 4

$$C = (1/N)\left(\Sigma \Delta d_i d_i^T\right) \tag{4}$$

Step IV: Diagonalization of the covariance matrix to obtain the eigenvectors, ν_k and the eigenvalues, λ_k.

Step V: Construction of the linear model as shown in equation 5, where $\nu = (\nu_1, \nu_2, \ldots, \nu_k)$ is the matrix of the first eigenvectors, and W_s is a vector of weights, also called the shape coefficient. This results in a shape model.

$$d = d_{mean} + \nu W_s \tag{5}$$

The shape variations by ±2 SD from the mean shape along the first two principal modes were generated using eigenvalues and eigenvectors derived from this analysis. These images were synthesized by setting the weights of the first or the second modes at $\pm\sqrt{\lambda_i}$ and $\pm 2\sqrt{\lambda_i}$ (where i = 1, 2 for the first and second eigen mode respectively) and all other weights to zero. The synthesized images provide a visual representation of the possible variance in shape of the cartilage based on 20 image sets to create the atlas.

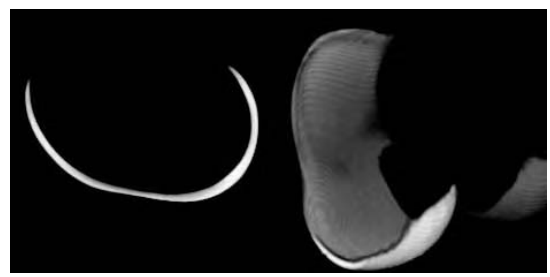

Figure 4 - Left: Shows the sharp edges on the atlas. Right: 3D volume reconstruction of the cartilage from the atlas

Results

The alignment of test image to the reference image using affine and freeform transformation is shown in figure 3. A region of interest is selected on the reference image and overlaid on the test, affine and the image obtained after free form transformation to show the accuracy of registration. It can be clearly seen that the affine transform corrects for positional and global scale changes and the local deformation corrects for physiological changes. The accuracy of the alignment can be visually evaluated by the sharp edges of the cartilage in the 2D images of the atlas as

Figure 5 - 3D active shape models. Average shape shown in the middle top row with standard deviation (SD) variations along the first and second mode shown in rows 2 and 3: Left to right - 2SD, -1 SD, +1 SD and +2 SD. Arrows indicate regions with changes from average bone shape

shown in figure 4. At the end of each iteration the reference image is replaced by the average image which moves closer to the centroid of the images in the group. There is no significant difference in the atlas after the third iteration confirming its convergence. Figure 4 shows 3 dimensional rendering of the cartilage generated from the atlas volume.

Figure 5 shows the active shape models and the variations in shape for ±2SD along the two leading eigenmodes. The outline of the cartilage is overlaid on the variations along the first and second modes that show the variations seen in the current set of 20 subjects. The first mode shows the larger changes since it captures the largest variation in the data as compared to the second mode.

Discussion

We successfully developed an atlas for the articular cartilage derived from the MR images at 3T. This is the first report of creating a cartilage atlas from images acquired at high resolution and isotropic resolution (0.365x0.365x0.365). The results show very accurate alignment which could be used for clinical purposes. We are currently working on creating a 3D Active contour without edges segmentation algorithm proposed by Chang T and Vesse L to extract the cartilage from the MR images.

We hypothesize that it is possible to automatically determine the cartilage location by analyzing its overall shape variation. If this hypothesis holds, then we can reverse the process and use the information obtained from the shape analysis to automatically segment cartilage from rest of the structures. In future we intend to use the active shape models and show that unsupervised learning can be used to explore the anatomy and facilitate segmentation. This methodology could potentially be used to classify different population groups. Structural shape characterization using PCA has been used to study gender and disease-related morphological differences in the corpus callosum, putamen, ventricles and hippocampus [20, 21]. It should be noted that within the scope of this paper we demonstrate the feasibility of generating the active shape models and that the application for classification will require far more image volumes to be included in the training set from the population cohorts of subjects under investigation.

Conclusion

We have developed an atlas for the cartilage and active shape models which when combined can be used to detect the subtle shape changes in cartilages. We see significant changes using this technique within the group of 20 subjects we selected. These models have a potential to be used in the future to discriminate normal and diseased states with larger databases.

Automatic Image Modality Based Classification and Annotation to Improve Medical Image Retrieval

Jayashree Kalpathy-Cramer[a], William Hersh[a]

[a] *Department of Medical Informatics and Clinical Epidemiology, Oregon Health and Science University, Portland, Oregon, USA*

Abstract

Medical image retrieval can play an important role for diagnostic and teaching purposes in medicine. Image modality is an important visual characteristic that can be used to improve retrieval performance. Many test and on-line collections do not contain information about the image modality. We have created an automatic image classifier for both grey-scale and colour medical images. We evaluated the performance of the two modality classifiers, one for grey-scale images and the other for colour images on the CISMeF and the ImageCLEFmed 2006 databases. Both classifiers were created using a neural network architecture for learning. Low level colour and texture based feature vectors were extracted to train the network. Both classifiers achieved an accuracy of > 95% on the test collections that they were tested on. We also evaluated the performance of these classifiers on a selection of queries from the ImageCLEFmed 2006. The precision of the results was improved by using the modality classifier to re-sort the results of a textual query.

Keywords:

medical imaging, neural networks, image annotation, content-based image retrieval

Introduction

Medical images form a vital component of a patient's health record. Effective medical image retrieval systems can play an important role in aiding in diagnosis and treatment; they can also be effective in the education domain for healthcare students, instructors and patients alike. As a result of advances in digital imaging technologies, there has been a large growth in the number of digital images stored in recent years. In addition to the Picture Archival and Communication Systems (PACS) that are becoming omnipresent in hospital and clinics, there are numerous on-line collections of medical images. On-line atlases of images can be found for many medical domains including dermatology, radiology and gastroenterology. The sheer volume of medical image data provides for numerous challenges and opportunities in the arena of medical image retrieval.

Historically, the task of indexing and cataloging these collections has been performed manually. This is an arduous and painstaking task, and is prone to errors. Consequently, there is a desire to be able to automate the task of indexing these collections with a goal to improve the ability to search and retrieve relevant documents.

Medical image retrieval systems have traditionally been text- based, relying on the annotation or captions associated with the images as the input to the retrieval system. The last few decades have offered advancements in the area of content-based image retrieval (CBIR) [1]. CBIR systems have had some success in fairly constrained medical domains, including pathology, head MRIs, lung CTs, and mammograms [2]. However, purely content-based image retrieval systems currently have limitations in more general medical image retrieval situations, especially when the query includes information about pathology [3, 4]. Mixed systems (using both textual and visual techniques) have demonstrated improved retrieval performance, especially with regards to precision at the top of the list [4].

Medical image databases used for image retrieval or for teaching purposes often contain images of many different modalities, taken under varied conditions with variable accuracy of annotation. This can be true for images found in various on-line resources, including those that access the on-line content of journals[1].

Image modality is an important, fundamental visual characteristic of an image that can be used to aid in the retrieval process. However, the annotations or captions associated with images often do not capture information about the modality. Images that may have had modality associated with them as part of the DICOM header can lose that information when the image is compressed to become a part of a teaching or on-line collection. There have also been reported errors in the accuracy of DICOM headings [5].

The medical image retrieval task within ImageCLEF has provided both a forum as well as test collections to benchmark image retrieval techniques. The ImageCLEF campaign has been a part of the Cross Language Evaluation Forum since 2003 [3]. CLEF itself is an offshoot from the Text REtrieval Conference (TREC). In 2004, ImageCLEFmed, a domain–specific task, was added to evaluate medical image retrieval algorithms and techniques.

1 http://gm.arrs.org/ (accessed 3/26/2007)

Approaches combining both visual and textual techniques for retrieval have shown some promise at medical image retrieval tasks [3]. In 2005, a medical image annotation task was added to ImageCLEF. The goal of this task was to correctly classify 1000 test images into 116 classes given a set of 10,000 training images. The classes differed primarily in anatomy and view of the image. It should be noted, however, that these images were primarily of a single modality (X-rays).The goal of the ImageCLEF medical image retrieval task of 2006 was to retrieve relevant images for thirty topics from a test collection of about 50,000 annotated images of different modalities. These tasks were divided by the organizers into those expected to be amenable to textual, visual, or mixed retrieval techniques.

We participated in both the medical image retrieval and the automatic medical image annotation tasks at ImageCLEF 2006 [6, 7]. The techniques developed for those tasks have been extended for the more general task of medical image modality classification and annotation.

Using medical image modality for image annotation and retrieval has recently been studied. Florea et al [8] have compared the efficacy of two different systems (MedIC and MedGIFT) in classifying the modality of a database with six standard modalities for radiology and nuclear medicine images.

In this paper, we compare the results obtained on our system with those described in previous publications [8] for the six modalities of the CISMeF database. We will also extend this technique to classify colour images from the ImageCLEF medical retrieval task collection [6] into six categories. We will finally report on the improvement in precision that we observed for a selected number of tasks of the ImageCLEF medical retrieval task for 2006 by incorporating the modality classifier in series with a text-based retrieval system.

Methods

We employed a supervised machine learning approach to problem of medical image modality classification using a hierarchical classification scheme as seen in figure 1. There were two primary databases that were used to create and test the classifiers. We worked with a small subset of the CISMeF database as the primary target for our grey-scale (radiographic and nuclear medicine) image classifier [9]. This database had a set of 1332 images classified into one of six classes based on modality. These include angiography, computerized tomography scans (CT), X-ray, Magnetic resonance (MRI), ultrasound, and scintigraphy. The images in this database had been acquired under differing conditions over a long period of time. Consequently, there was considerable intra-class variation in quality, size, contrast, illumination and background.

The imageCLEFmed database contains 50,000 images of differing modalities, including radiography and nuclear medicine, as well as microscopic and histopathological images, photographs and gross pathology images, power point slides, electroencephalograhical images (EEGs) and electrocardiograms (ECGs), as well as a few miscellaneous images.

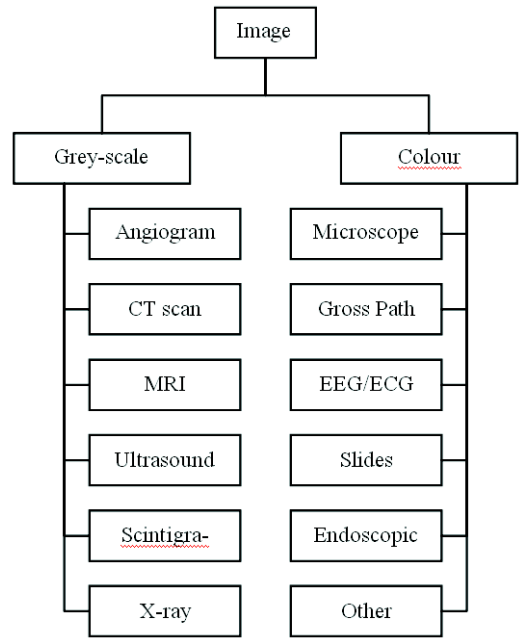

Figure 1 - Hierarchical classification scheme for images

A neural network-based scheme using a variety of low level, primarily global image features was used to create a six-class classification system for the grayscale images. The multilayer perceptron architecture used a hidden layer of approximately 50-150 nodes. The classification system was created in MATLAB[2], in part using several routines modified from the Netlab toolbox[3].

We experimented with a variety of feature vectors as inputs to the network. A combination of texture and intensity histogram features provided the best classification [10, 11]. All images were first resized while maintaining the aspect ratio such that the smaller dimension was 256 pixels. The image was divided into five overlapping blocks. Grey level correlation matrices were computed for each block using four angles and an offset of 1 pixel. Contrast, correlation, energy, homogeneity and entropy were calculated for each matrix. A quantized grey scale histogram was then appended resulting in a 132-dimension feature vector for each image for the texture. All inputs to the neural network (the image feature vectors) were normalized using the training set to have a mean of zero and variance of 1.

The 1332 images in the database were randomly split into a training set of 1000 images and a test set of 332 images. A small random subset of the training images was initially used to create the classifier (200 images). The classifier

2 www.mathworks.com (accessed 3/26/2007)
3 http://www.ncrg.aston.ac.uk/netlab/index.php (accessed 3/26/2007)

was then applied to the entire training set and images that were misclassified were then added to the images used to refine the classifier. The classifier was finally tested on the test images.

A similar scheme was used to create the classifier for colour images. We believe this novel idea can improve the retrieval performance of purely textual systems or for images for which the associated modalities are not known. Although modality detectors for grey-scale medical images have been reported [9], we are unaware of a similar effort for classification of other categories of medical images like those produced by histo-pathology and endoscopy. The images used for this classification task were taken from the test collection of images used in the ImageCLEFmed retrieval task. 2250 colour images in this collection were broadly categorized into six categories as microscopic, gross pathology, EEG/ECG or other charts, powerpoint slides, endoscopic images and other. There was considerable intra-class variability in this dataset. These 2250 images were again split randomly into training (1750) and test images (500). A similar training methodology to that described above was used to incrementally improve the classifier, starting with a smaller subset of the training database.

A two-layer architecture with 25-150 hidden nodes was used for the neural network. The feature vector in this case consisted of colour histogram features, as well as texture features obtained using the grey level correlation matrices. The image was split into 9 uneven blocks. Colour histogram properties of image after conversion into the L*A*B* colour space were calculated, while texture features were calculated after converting the image to grey-scale

These neural network classifiers can be created to further classify images within a given modality. For instance, x-ray images could now be classified to account for anatomy. Anatomical classifiers were used in the automatic annotation task at ImageCLEFmed.

The tasks had been stated in English, German and French, and had and provided example images. All but three of the tasks stated the desired modality of the image to be retrieved. Two examples of the tasks are shown in figure 2.

Show me images of a hand x-ray.
Zeige mir Röntgenbilder einer Hand.
Montre-moi des radiographies de la main.

Show me blood smears that include polymorphonuclear neutrophils. Zeige mir Blutabstriche mit polymorphonuklearer Neutrophils. Montre-moi des échantillons de sang incluant des neutrophiles polymorphonucléaires.

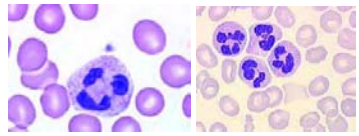

Figure 2 - Sample textual and visual queries at ImageCLEFmed 2006

Once our classifiers had been trained to achieve >95% classification accuracy, they were tested on a random subset of the ImageCLEFmed topics.

The schematic of our modified retrieval system is shown below. The query was initially fed to our Lucene[4] based text retrieval system. The queries were manually edited by one of the authors. The resulting images were subsequently classified by the hierarchical classifier for modality. Images of the desired modality (as stated in the query or as discerned by the automatic classifier based on the sample images) were moved to the top of the list while maintaining the ranking of the textual system within a class.

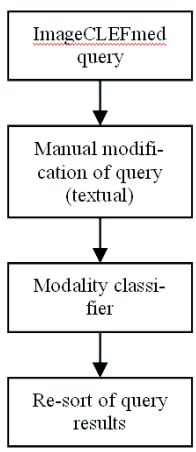

Figure 3 - Image retrieval system used for the ImageCLEFmed 2006 test collection

We compared the results of our purely textual system with that including the addition of the modality classifier.

Results

A classification accuracy of 96.4% was achieved on the CISMeF database. The confusion matrix suggests that the primary misclassification occur between the MRI and CT scan classes. This is not surprising as these classes are visually quite similar. Florea et al [8] have reported similar results both in terms of accuracy and inter-class misclassification patterns. The classification of grey-scale medical images into commonly occurring modalities using low level image features and machine learning techniques appears to be a tractable task. We expect to achieve over 98% accuracy with further refinement of our machine

4 http://lucene.apache.org/ (accessed 3/26/2007)

learning approach by the use of more advanced cross-validation, bootstrapping, boosting or bagging techniques.

Preliminary testing of the classifiers on 2250 colour images of the imageCLEFmed test collection resulted in a modality classification accuracy of 98.6%. Most of the misclassifications involved the "other" class with contained a set of miscellaneous images not belonging to the other five specific categories

The colour modality classifier was tested on a small random subset of the ImageCLEFmed 2006 topics. The topics for imageCLEFmed 2006 fell into three categories (visual, mixed, semantic) consisting of 10 tasks each. Although visual techniques had, in general, performed extremely poorly at the semantic tasks, use of some visual information (primarily modality) was shown to increase the precision [4].

Analysis of our textual results indicated that in many queries, especially those of a visual or mixed nature, up to 75% of the top 1000 results were not of the correct modality. A compelling example is given in figure 4 and table 1. Only 90 of the top 2000 images returned by the textual query were of the desired modality.

Task 1 - Show me images of the oral cavity including teeth and gum tissue

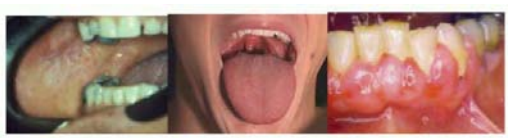

Image type	Number of images
Total returned by textual query	2000
Grey-scale	1831
Photograph/gross pathology	90
Microscope	71
Other	8

Figure 4- Sample query suitable for visual retrieval at ImageCLEFmed 2006

These images were then classified using our modality classifier. The ranked list of retrieved images was resorted taking into account the desired modality based on the query.

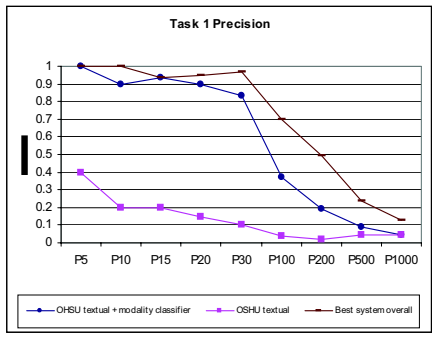

Figure 5 - Improvement in precision resulting from modality classification.

Figure 5 plots the precision for varying number of documents retrieved for the purely textual system, the improvement with the use of the modality classifier and the overall best system (mixed visual and textual based) that participated in ImageCLEFmed 2006. This increased the precision of the query as seen in figure 5. The improvement in precision at the top of the ranked list (P5 – P200) is better with the use of the modality detector compared to a purely textual search. We should note that a perfect modality classifier will only improve the precision of the search and not the recall if it is applied in the serial manner described above. The mean average precision (MAP) would still be limited by the number of relevant images that are retrieved by the textual search (recall of the textual search).

Even in searches that are expected to be semantic, we see an improvement in precision by using the modality classifier as seen in figure 6 and 7.

Task 2 - Show me microscopic images of tissue from the cerebellum (semantic query)

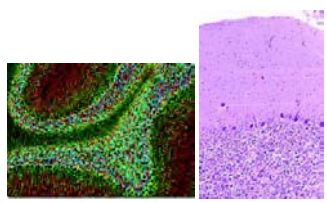

Image type	Number of images
Total returned by textual query	2000
Greyscale	1476
Photograph/gross pathology	408
Microscope	116

Figure 6 - Sample query suitable for visual retrieval at ImageCLEFmed 2006

The precision of this search was similarly improved by the use of the modality detector as seen in figure 7.

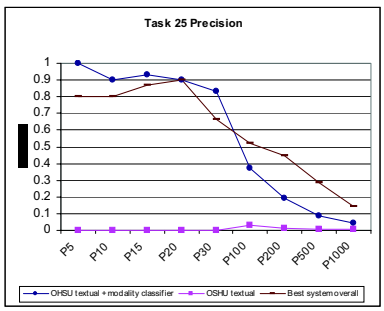

Figure 7 - Improvement in precision resulting from modality classification

Four of the six tasks tested showed improvement in precision by the use of the modality detector for colour images. There were two tasks amenable to textual methods for which there very little change in precision with the addition of the modality information.

We plan on testing the performance of the modality detector on the complete set of tasks for ImageCLEFmed 2005 and 2006. We also intend to index the entire collection of 50,000 images used in the ImageCLEFmed test collection using the modality classifier. Information about the class membership of an image will be added to the metadata. This should improve the performance of the retrieval in two ways. Clustering of the data by modality and perhaps anatomy will speed up the search process as fewer documents will have to be compared to the query image/text. Secondly, we expect that the overall precision of the search will improve by considering the modality of the image that is desired by the user. However, we can expect a small degradation in the recall due to potentially misclassified images not being searched.

Conclusion

We have developed a neural network based, hierarchical classifier for the modality classification of medical images. This system can classify colour images including histo-pathological and endoscopic images, and photographs as well as grey-scale (radiological and nuclear medicine). The classifier uses a histogram and texture properties as inputs to the two level neural network. This classifier results in a classification accuracy of greater than 95% for the grey-scale images of the CISMeF database as well as a selection of colour and grey-scale images from the ImageCLEFmed database. The use of this classifier increases the precision of retrieval of our primarily text based retrieval system by moving images of the desired modality to the top of the ranked list.

Acknowledgments

The authors would like to thank Henning Müller for his valuable input in discussions as well as providing access to the CISMeF images. We would also like to thank Jean-Nicholas Dacher at the Rouen Hospital, France, for proving the CISMeF images used in this paper. We would like to thank Dr. T. Lehmann at RWTH Aachen University, Germany, for access to the IRMA image database. We acknowledge the support of NLM Training grant 5T15 LM07088-15 and NSF Grant ITR-0325160.

Quantification of Myocardial Perfusion for CAD Diagnosis

Hartmut Dickhaus[a], Markus Erbacher[a], Helmut Kücherer[b]

[a] *Department of Med. Informatics, University of Heidelberg, Heidelberg, Germany*
[b] *Department of Cardiology, University Hospital, Heidelberg, Germany*

Abstract

We introduce a computer based algorithm for objective quantification of myocardial perfusion to support the diagnosis of cad patients. This new method is based on conventional cine angiographic films. In order to achieve maximal quality of the digital subtraction angiography images, the sequence is synchronized with the ECG. Optionally, the digital images can be motion compensated by a two step matching method. The spatio-temporal spread of blood, or the so-called blush, through the microvasculature to the myocardium - indicated by dye injection – represents a characteristic pattern for the myocardial perfusion. This dynamic temporal pattern is characterized by typical features as the maximal value of blush intensity, of increase and of decrease velocity which correspond with the different phases of flooding in and washout. On the basis of 100 different temporal blush profiles, an algorithm is established which classifies the acquired blush patterns into 4 different grades.

Keywords:

angiography, blush grade, CAD diagnosis, myocardial perfusion

Introduction

Currently, the coronary angiography is still the gold standard for coronary artery disease (CAD) diagnosis, although other methods have been proposed and discussed [1]. In almost all cases, the required invasive procedure of inserting a catheter for dye injection is combined with a percutaneous transluminal coronary angioplasty (PTCA). Therefore, the angiographic procedure allows an immediate estimation of the success of the therapeutic intervention.

For quantifying complete and sustained reperfusion of the infarcted myocardium and prognostic statements as for identifying patients at high risk, myocardial blood flow, expressed in so-called blush grades, is much more appropriate than any other angiography related measure. This is demonstrated by Stone et al. [2].

However, so far only qualitative descriptions for different extends of blush or myocardial reperfusion exist. Gibson et al. [3] presented 4 different grades which classify the perfusion in relation to its temporal dynamic and intensity. For example: grade 1 is defined as: "dye slowly enters but fails to exit the microvasculature. There is no blush or opacification on the myocardium in the distribution of the culprit lesion that fails to clear from the microvasculature and dye staining is present on the next injection 30 sec later."

Despite the principal advantages of blush characterization, qualitative descriptions like these are difficult to apply in an objective and reproducible stratification. For that reason, we tried to establish a computer assisted procedure to quantify blush grades corresponding with those of Gibson, however, in an objective and formal description. Furthermore, we developed a computer aided tool to visualize the spatial and temporal spread of the adelomorphic blush, of the myocardium from cineangiographic films after dye injection into the arteries. Under the control of the cardiologist, a specific blush grade is assigned for a specific myocardial region related to the three main supplying coronary arteries.

Materials and methods

In this study, 100 films from patients with various extent of CAD recorded in different projections, are quantitatively examined before and after PTCA. Because the heart is supplied by three different arteries: right coronary artery (RCA), left artery descending (LAD) and left circumflex (LCX), we look for blush occurrence in correspondent myocardial areas supplied from these vessels.

In order to enhance the contrast between blush and the arteries and surrounding tissue, images after dye injection have to be subtracted from that prior to injection, respectively in standard position. The initial image without dye is called a mask and is mostly established by averaging two or three consecutive frames in order to smooth small artifacts and noise. The difference of images shows the highest contrast between filled vessels, microvasculature and the surrounding, if we take the logarithmically transformed angiograms. In order to consider the motion of the heart and its vessels as well as the inserted catheter during the heart cycle, one has to choose images for subtraction which correspond to identical heart geometry and position. This can be achieved by synchronization of the image acquisition to the R peak of the simultaneously recorded ECG. Fortunately, the time interval between two cycles,

about 1 sec, is relatively small, so that the resulting time course of dye spreading is still sufficiently documented.

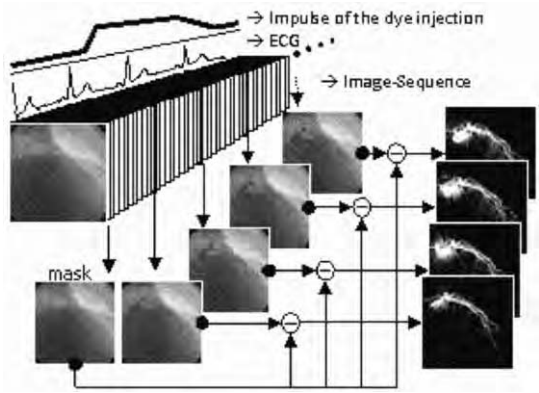

Figure 1 - Acquisition of ECG synchronized frames from the cine angiographic film. The black marked frames related to the R peak of every cardiac cycle are used for creating the sequence of difference images, displaying the spreading blush across the heart.

In figure 1 the acquisition procedure is schematically demonstrated. With increasing time we get a sequence of difference images displaying the temporal progression of dye and its spatial spreading through the arteries and small vessels into the microvasculature and the myocardium. The quality of these images demonstrating the blush is highly dependent to any change of body position or motion of inner organs, like the diaphragm, during breathing. For this reason, the patient is asked to stop breathing for about 20 sec, and the camera as well as the operating table have to be fixed for that period. However, in clinical routine it is difficult to accomplish these conditions completely. Therefore, we apply additional compensation procedures in two consecutive steps.

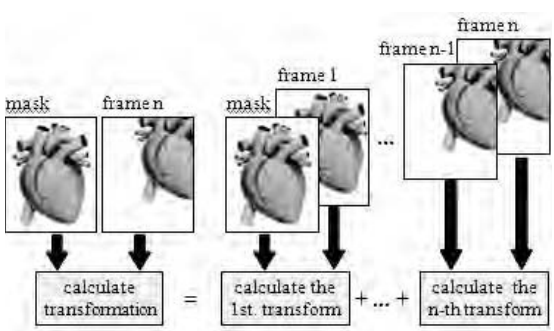

Figure 2 - Schema of the registration procedure between frame n and the mask: the registration is split into n single consecutive transformations and finally the sum of all transformations is performed.

Movements of the operation table or of the camera adjusted by the cardiologist for optimal viewing conditions are primarily compensated by a rigid matching procedure. Secondly motion of the inner organs particular caused by breathing needs an elastic compensation. In most cases the table or camera movements are larger but can be corrected more easily than the breathing effects. This two step procedure minimizes the extent and time for the elastic registration [4].

One general problem characterizes both registration steps, even the continuous spread of dye during the digital acquisition procedure. This means that besides the mentioned motion artefacts we have to consider differences between succeeding frames resulting from the dye distribution. In order to minimize this problem we apply the matching procedures always between two consecutive image frames. That means that the registration is performed every time relative to the previous frame. Finally all single transformations are summed up. Figure 2 demonstrates this process schematically. To calculate each transformation step, the rigid one as well as the elastic one, primarily the vessels have to be segmented for each frame. The pixels identified as vessels are then skipped during the calculation, in order to minimize the problems caused by the spreading dye.

The spatial distribution of the blush is represented by the gray value averaged from myocardium pixels excluding the arteries. That means we have to identify all myocardium pixels belonging to the blush. This task is very hard even for an experienced cardiologist. We perform this segmentation by an interactive procedure. For all pixels, we trace the intensity profile, respectively the gray value, over time. The incoming wave of dye after injection follows primarily the main coronary arteries, flows through the smaller vessels into the microvasculature, and reaches the myocardium. The washout is collected in the venous vessels. This time dependent process can be represented in its spatial distribution by detecting the maximal values of the intensity profiles of all image pixels. All pixels identified by their maximal gray values at a certain time instant represent more or less a specific structure of the pathway to the venous system. As it is demonstrated in Figure 3, it is easy to choose a color map representing the arteries map c) or d) or the perfused myocardium, pixel map f). For all segmented pixels of map f) we calculate the average gray value, cycle for cycle and plot the corresponding time course of blush intensity.

The cardiologist has to position a specific ROI at a region of the myocardium besides the arteries where a blush would be expected under normal conditions. We also calculate for this specific region the average gray values for different instants of time as characteristic time courses for a restricted perfusion. The different time dependent profiles have to be characterized by a few parameters which can be used to distinguish between different grades of blush. Furthermore, we would like to define parameters which can be easily interpreted in context with the existing qualitative characterizations of Gibson, and finally they should be related to the pathophysiological background.

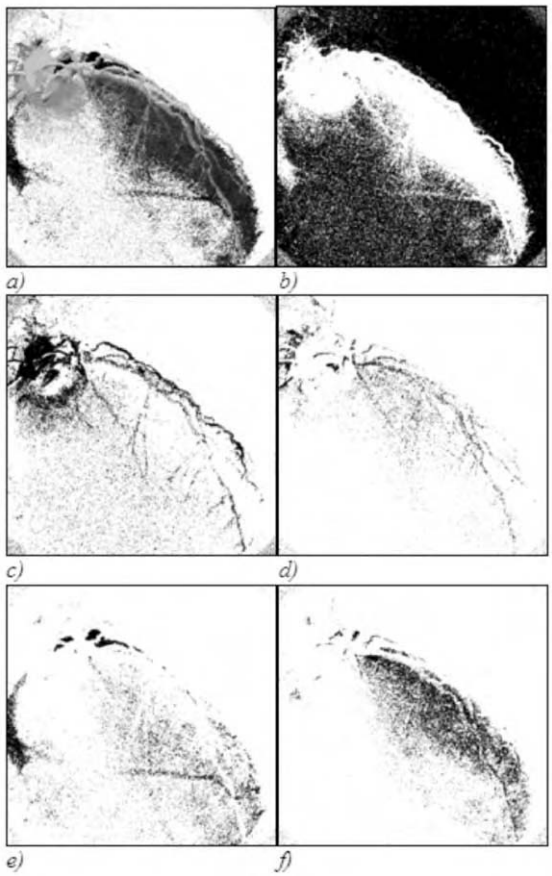

Figure 3 - Color maps for characterizing of specific structures during blood perfusion. The temporal incidence of the maximal dye intensity is mapped on to the pixel matrix. For different instances of time, corresponding with map b) to f), we display different anatomic structures which are perfused at this time; a) shows all maps superimposed: background, artery (LAD), branching, myocardium, vein; b) - f) the separated structures. Map f) is of particular interest because it represents the pixels of the myocardium.

We defined 4 different parameters for each intensity profile which are displayed in Figure 4: the maximal intensity Gmax; the time of Gmax; the maximal slope Imax of the rising profile, which corresponds with the maximal rising velocity of the perfusion; and the maximal slope Dmax of the falling profile, which corresponds with the maximal outwash velocity. For all calculated blush profiles, these four parameters are extracted as a typical characterizing feature set.

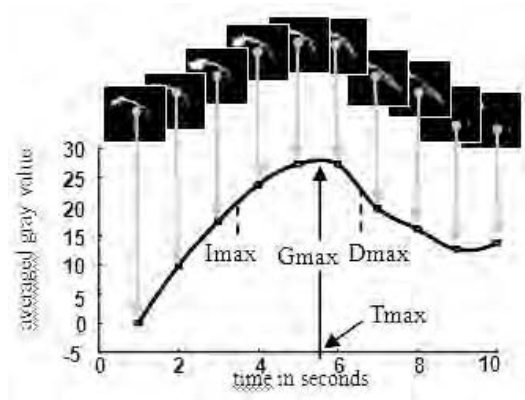

Figure 4 - The time course of averaged gray values from corresponding areas of the perfused myocardium. 4 specific parameters: Imax: Increase-slope, Dmax: Decrease-slope, Gmax: maximal gray-value, Tmax: time of Gmax are indicated

Results

For all 100 films the corresponding time courses are established and automatically characterized by Gmax, Tmax, Dmax and Imax. It is of particular interest to demonstrate the difference of blush spreading before and after a PTCA intervention by different temporal patterns.

Different degrees of stenosis are related with different extensions of blush and different patterns of dynamic profiles. The patient of Figure 5 had an occlusion of RCA. After PTCA the artery looks absolutely normal (Figure 5, lower trace). By positioning of a ROI in the supply area of this vessel we calculate the corresponding blush profile with its characterizing parameters. However, for the same region before PTCA we found a very flat profile (Figure 5 upper trace), which shows us that there is not any perfusion of the myocardium. Nevertheless, the reperfusion after PTCA is obvious. In this case we have consistent results with the re-opened artery and the blush profile. However, sometimes the situation demonstrated on the angiograms is not so clear. For these cases we get much more information by the quantified blush profiles.

In order to relate the various blush profiles to blush grades a non-parametric classification procedure based on the four specific parameters is under development. First promising results are in good agreement with the subjective grading of clinical experts.

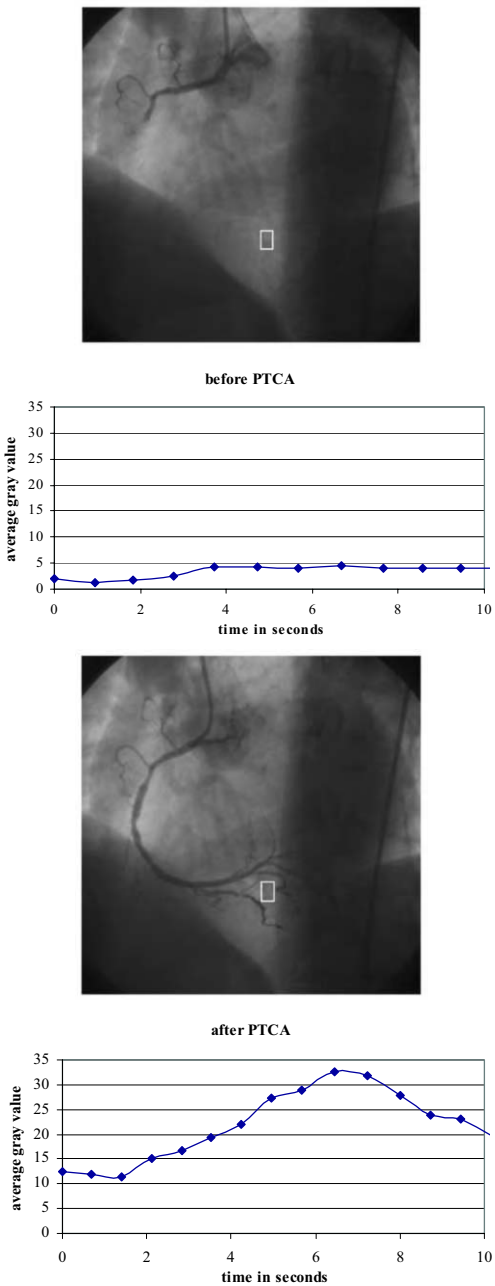

Figure 5 - Angiograms before and after PTCA of a patient with a complete stenosis of 100% for RCA. The corresponding temporal blush profiles document obviously the improvement of myocardial reperfusion

From the 100 digitized angiographic film sequences we could evaluate only 60 without considerable motion compensation. The introduced two step registration method allowed an additional evaluation of 30 more series. The remaining 10 films show such considerable motion artefacts of the diaphragm that an evaluation was not possible. In all of these cases the diaphragm moved over the whole hearth and modified its grayvalues significantly. Figure 6 shows the effect of motion compensation.

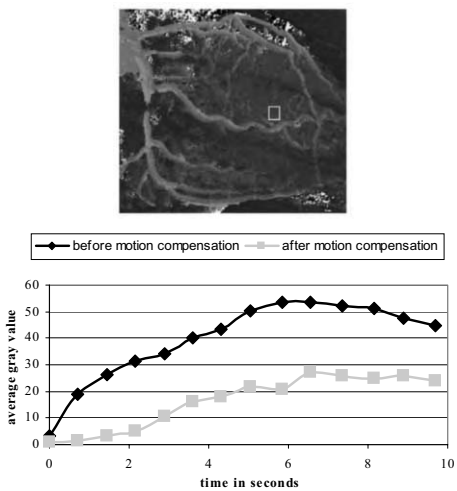

Figure 6 - The left image shows the extent of usually recorded motion artefacts whereas the right image demonstrates the benefit of motion compensation. The time courses before and after motion compensation are plotted in the same diagram below

Discussion

Our presented approach on the basis of digital subtracted angiographic images is an interactive procedure which helps the cardiologist to assign blush grades in strong relation to what he is used to do. He gets an intuitive impression of the spreading blood after the dye injection by displaying the processed colormaps. It is easy to confirm a quantitative hypothesis by looking precisely to selected areas of interest of the myocardium, and its temporal gray value profile or to integrate the average dye activity of the whole area.

The advantages of the developed system are given in a highly adaptable degree of automation. Dependent on the quality of angiograms, the more or less experienced user can interfere in different kinds. For example, simple adjustment of the contrast or corrections of motion artefacts lead to an improved quality of the digitally subtracted image sequence. The automated classification procedure is also easily adaptable to other types of blush patterns. Up to now it was our aim to implement the descriptions for blush grading of experienced cardiologists as it was proposed by Gibson. However, if we wish to characterize any other specifity of the perfusion, we can as well introduce more quantitative features related to the blush patterns, for example temporal measures. Furthermore, other approaches of motion compensation could be incorporated and evaluated for their practicability in respect of typical

angiographic artefacts. Of course, we have to look for more sequences to incorporate them in our learning sample. Therefore, we developed an intuitive user interface which helps the cardiologist to follow the different steps of the acquisition procedure and which offers him the various facilities to derive a reliable diagnostic statement. During the current evaluation of our system we are discussing the usefulness of a more automated selection of the ROI for blush profile quantification. However, up to now the experienced cardiologists are not convinced that this feature increases the clinical benefit significantly.

Abstract

Sound understanding by end-users (health professionals and support staff) of key e-health principles and challenges is essential for the safe, effective, and sustainable use of health informatics systems. This is separate from, and ideally a precursor to, training on a specific system. However, hitherto this aspect has been little understood or addressed. Over the last few years, the concept of a customised Health Supplement to the well-established European/International Computer Driving Licence has progressed from idea to reality, through initial support for consultation by the then UK NHS Information Authority, followed by establishment of an international Expert Group by the global ECDL/ICDL Foundation. As a result, the ECDL/ICDL Foundation has developed a formal syllabus. This paper reports successful piloting, and progress in the development of local training and testing materials and national implementation plans, in three countries on two continents.

Keywords:

health informatics education; end-user; ECDL; ICDL; health informatics sustainability

Introduction

As defined by the theme for Medinfo 2007, there is rapidly growing recognition and dependence in all countries on the future major role of health informatics systems in enabling national health systems to be increasingly effective, efficient, and evidence based. Whilst each country starts from a different base line, all are moving forward at their local pace in increasing the use of informatics systems.

Rightly, the priority is increasingly for sustainability, which must include the reliable and efficient use of such systems, in line with intention and with capability. However, the fundamental oversight is to focus solely on systems design and implementation, important though they are. What is so often overlooked is the fact that systems are only as good as their users' understanding and capacity to use them appropriately.

Health informatics systems are a vehicle for collecting, processing, and making available relevant health information at the point of need. Therefore such support systems should not dominate or hamper health practitioners' activities except so far as they can make them more effective or efficient. However, all too often end users – health practitioners and their support staff – can find such systems threatening and restricting, and in turn this means that systems are used inefficiently and ineffectively, and either perform badly or fall into disuse.

Resistant mature staff

Though often a surprise to many, this picture of end-user poor compliance is well documented over a period of time, and thus should be anticipated [1]. Health professionals have in round terms a professional lifespan of approximately forty years. In nearly every country those practicing for more than ten years will have undertaken their basic professional education and early practice in an environment based on paper-based records. In many countries of the world electronic systems will only have been brought in even more recently. Furthermore, the most senior and experienced health practitioners – usually the professional champions and leaders – will certainly have been educated ahead of the e-health revolution. It is into this workforce environment that governments, health policy makers, and health informatics system advocates are seeking to introduce radical and comprehensive electronic systems.

An atypical IT system user population

A further complication is that not only are health information system end users more well versed in paper-based systems, in many other ways too they differ from the end users of almost all other organisation-wide modern electronics records systems, such as those in banking or the travel industry [2,3]. Not only are health users senior and mature staff rather than new entrants; they are totally dependent on information systems in order to carry out their principal daily business. However, this core work is not itself focussed on the information system - in general the use of the information system only forms between 10% and 20% of their duties - and to them this is a low-skill element of their work. Thus senior doctors, nurses, and other

Selected for best paper award.

health professionals will not give the same level of importance to being trained in new-generation information systems as they will to new clinical or healthcare techniques. Yet, even though being only part-time users, they are senior and often autonomous employees, and they have professional accountability over and above their duty to their immediate employer. Thus they will only be effective, reliable and regular users if they both understand the way to harness a system, and trust in its integrity and that of all partner users (who are largely unknown to them individually). The deeper analysis undertaken of these differences of health informatics system end user profiles compared to others system user profiles has been published [2, 3].

Change-inducing systems

Added to these challenges, health informatics systems in themselves do not support clinical practice in the simplistic ways that telephones support and replace meetings and written correspondence, or dictation systems replace the need for the physical presence of a secretary. Instead, health information systems require a very different pattern of working, ranging from new data recording processes, through to how to search a past record (which is navigated very differently if it is held in computer files compared with if it is a large collection of paper charts in a physical folder).

Informatics system sustainability but practice challenge

Therefore sustainability is highly dependent as much upon the pattern of use as it is on the pattern of design, yet is affected also by the user population's characteristics. Thus it is clearly naive to expect the complete cohort of the most senior and experienced practitioners in their country universally to welcome and endorse new systems which require radically different physical and cognitive skills, and which require immediate changes to patterns of data recording and assimilation honed over a life time. Thus, however good the system introduced, it will not be sustainable if the principal stakeholders are not comfortable with issues.

Counteracting the principal risks of health information systems

Apart from recognising the challenge to traditional practice of new health informatics systems, it is also important to recognise the inherent risks these bring if introduced without due preparation. Moreover, professionals will be aware in general terms of these risks, and be likely to militate against introduction of such systems with good intent unless they feel that these risks have been addressed and controlled. There are three types of such risk, as shown below.

Risks generated by the need for new skills

The use of a health informatics system requires a radical range of new skills. These commence with the basics of operating any computer system, through the skills required to record data electronically as apposed to by hand writing or filing a chart, to the skills needed to navigate a record which is stored in a highly structured and efficient way but which needs a new mind set in order to negotiate it effectively to find key and relevant information items. It would be unreasonable to expect a surgeon to use a new type of instrument or a radically new surgical procedure without adequate training, yet governments and policy makers worldwide are inappropriately labelling as "obstructive" health practitioners who are reluctant to change information management approaches with which they are familiar, for ones which they find unknown and intimidating. Further, 'smart' systems may make good evidence-based calculations, recommend particular treatment patterns or warn against particular prescribing intentions. These are safe provided the end user understands the rationale in both the clinical and computing logic inbuilt, but carry risks if the end user does not understand and know how to ascertain that logic.

The risks of new constraints

A key aspect of most health informatics systems is the fact that they require a standard approach to the description of histories, investigations, results, diagnoses, and interventions - in other words, the benefits of standard terminologies and taxonomies should reduce ambiguity and render observations and findings interpretable accurately by all. However, the converse of that is that an individual's well-developed means of indicating valuable subjective information such as uncertainty, provisional views, or feelings as apposed to hard evidence are rendered impossible. This may either exclude uncertain information, or result in it being recorded with a spurious impression of certainty. Users may know the clinical approach and specific skills of colleagues who hand-record narrative information, but this authorship and personalisation may be lost with electronically captured and stored data.

Risks of misuse

The very strength of health informatic systems – that they can search and present information from very large databases extremely quickly – is a potential risk as well as being a core purpose. Files can become increasingly comprehensive, and information can be obtained about many people. Careless use of such information can lead to inappropriate divulgence of confidential information, and without safeguards there are clearly risks of an ethical or malicious misuse. Thus all end users need to be educated to avoid these risks, and to adhere to robust corporate policies to control usage.

For all these reasons it is therefore important for end users to be adequately educated as to how to use systems soundly and effectively. This is a key part of the sustainability of systems. Evidence (or even suspicion) of misuse of systems, or of poor clinical decision making because of inability to use systems, will provide a rapid means of ensuring their demise. Such evidence or suspicions may come either through professional sources, press reports, or collective patient anxieties.

The move to a health end-user qualification

The need to recognise end users

The educational needs of end users are very different from those of technical health informatics staff. Over a decade ago a European Commission Concerted Action entitled EDUCTRA identified the informatics educational needs of health professionals as being different from those of IT staff [4]. This work suggested a range of necessary learning outcomes for each group – though for health professional users they focussed primarily on basic curricula for new entrants. Subsequently the International Medical Informatics Association (IMIA) addressed this topic, and produced recommendations of what should form the basis of health informatics education globally for each of the two staff communities. Both before and since these recommendations, the prime focus has been on informatics education, with development of many formal courses, and on the introduction of some informatics training into basic health professional education. Neither of these groups, however, form the general body of the practice community to whom new organisation-wide informatics systems are introduced or imposed.

The concept of an end user qualification

To overcome these anxieties and risks it seems self-evident that an appropriate end-user educational programme, and related qualification, for health informatic systems users should be developed, but this was not being addressed. Meanwhile, virtually all countries in the world have a qualification requirement for drivers of motor vehicles or pilots of aeroplanes, as such equipment is seen as extremely beneficial yet extremely risky if misused through ignorance or lack of skills. It is seen as a societal responsibility to provide a qualifications framework and regulation, and a citizen responsibility to ensure qualification before becoming a user.

This approach has already been taken with the more general use of computers, with the development of the European Computer Driving Licence (ECDL) to a standard international curriculum, as most of the issues of using computers safely and effectively are generic and universal. This has now developed into the global International Computer Driving License (ICDL), available in virtually all countries of the world [6].

It therefore seemed logical to develop a specific supplement or module for the ECDL/ICDL, given the risks and responsibilities inherent in using such systems. This concept was first promoted in 1999 in a European context [7]. Subsequently, the idea was developed at conceptual level in more detail, and support gradually developed [8]. Of significance for Medinfo 2007, details were sought by a principal Australian health informatics journal [9].

Practical steps to development

Following these moves towards the development a health supplement to the ECDL/ICDL as the best means of meeting this need, and thereby ensuring sustainable and safe implementation of health informatics systems through education, assurance, and empowerment of end users, many practical steps have been made towards achieving this reality.

In 2004 the NHS Information Authority, the then lead body in this field for the National Health Service in England, agreed to support two consultation workshops – one for key opinion leaders in health informatics from eight European countries, and one for a range of delegates from the National Health Service across the United Kingdom. As a result of the strong enthusiasm at both these meetings, the European Computer Driving Licence Foundation (the global regulatory and licensing body for the ECDL/ICDL) agreed to consider formalising the development process. The ECDL Board endorsed this, and in 2005 an Expert Group was set up comprising representatives of six European countries and of the United States of America. The resultant recommended syllabus was signed off by the Expert Group in early 2006.

The ECDL/ICDL health supplement content

The final ECDL/ICDL Health Supplement consists of a competencies framework defining knowledge and skills the candidate needs to possess in order to operate a health information system safely. It excludes generic issues covered in health professional training or staff induction (such as basic principles of confidentiality). Regarding computer recording, it focuses on those aspects which are different, or have different emphasis or importance, in health applications.

The core contents of the syllabus are copyright to the ECDL/ICDL Foundation, and comprise the following topics:

- Concepts
  - Health Information Systems
  - HIS Types
- Due Care
  - Confidentiality
  - Access Control
  - Security
- User Skills
  - Navigation
  - Decision Support
  - Output Reports
- Policy and Procedure

For each topic a number of defined knowledge areas or competencies are specified. The content is designed to accommodate specific national language and terminologies, organisations, and legal and professional frameworks. The normal pattern of assessment will be electronic, through a testing framework available on line or by other electronic means. It is based on the assumption that the candidate will already be competent in basic computer user skills.

International trials and validation

Since the specification phase, rapid progress has been made in significantly different countries, with very differ-

ent health systems, different languages, and also different terminology and nomenclature within the same language group.

United Kingdom

In the United Kingdom, the British Computer Society as national licensee for the ECDL, and with a strong relationship with the National Health Service, organised piloting of the syllabus utilising an interim training manual and testing framework in six very different sites. These encompassed very different localities, and different healthcare environments ranging from primary care through secondary care to mental health, and different health professions from research staff to medical consultants, and also health informatics and health data experts. This pilot involved 84 persons, who were all very positive on the value of the knowledge and competencies covered in the syllabus. The only significant comments received were about the interim testing framework, which was only ever intended to be temporary in order to facilitate consideration of the syllabus. More detailed reporting of these results is in press [10].

Consequent upon these successful pilots, a full electronic training resource has been developed from the interim one, and a definitive electronic testing framework built. The ECDL Health Supplement was launched to English NHS staff by NHS Connecting for Health in April 2007, with the on-line tutorial and testing available to staff free of charge.

United States of America

The American Medical Informatics Association (AMIA) and the national ICDL licensee, ICDL-US, worked closely during 2006 to create a US-version curriculum for 'anyone in a health-related entity who touches a keyboard containing person-specific health information' as well as an examination to certify mastery of this content. This will be entitled the Digital Patient Record Certification or DPRC. The curriculum group adapted the syllabus developed by the ECDL Foundation group; the US version was then reviewed by the ECDL group.

The test will be piloted in early 2007 with the expectation that the program will be functional late in 2007. ICDL-US and AMIA found the partnership to be mutually beneficial and there is a desire to work together on other products for the North American region.

AMIA has two major educational initiatives underway and this initiative is part of its "Got EHR?" campaign. AMIA also seeks to educate the general public about electronic health records and especially integrated personal health records, particularly as an integral part of the electronic medical record. The campaign also strives to increase the use of EHRs in small practice environments. The second initiative is the "10x10" Program, which is an effort to educate 10,000 applied clinical informaticians by 2010. This program now involves two universities and will involve at least five by the end of 2007.

Italy

The Italian Association for Computing and Automated Calculation (AICA), the Italian national ECDL licensee [11], instructed CERGAS Bocconi to work out the Italian health syllabus, based on the core syllabus, and the test structure. The related "ECDL Health Manual" has also been developed and printed. Between January and March 2007, Italy has implemented two pilot editions of the course, delivered to about 60 medical doctors and nurses of the Local Healthcare Units of Milan and Dolo (Venice). Participants have been offered four courses of ECDL Start (24 teaching hours), plus a specific course of ECDL Health (8 teaching hours). At the end of the pilot courses, in May 2007, final examinations will be held and skill cards issued accordingly (including, for the first time ever in Italy, those relating to ECDL Health). The examination to obtain the ECDL Health skill card will include practical exercises simulating the use of patient records management software. The courses will be included in national and regional programmes aimed at the continuous education of the NHS medical personnel and will enable participating medical doctors to obtain some compulsory education credits. These courses are expected to become a key element of the education and training programmes nationwide.

The Italian experience stands out for its special focus on the preliminary planning of the initiative, also being based on a scientific research project conducted in 2004 aimed at measuring the potential benefits of information education and training in the healthcare sector [12]. This research project has analysed and evaluated the "cost of IT ignorance" in the Italian healthcare sector through a sample survey, empirical measurement tests, and experience of a similar research project conducted on private businesses. Ignorance in the information field has proved to be a notable hidden cost for the Italian healthcare sector and the potential value of information education and training of the NHS personnel amounts to about 2 billion Euros per year. After being published and officially presented, the results enhanced the institutional awareness regarding development of targeted educational programmes.

Discussion

Development of any new qualification takes a considerable period of time, commencing with identification of the need. This initiative has sought to achieve this in a way that matches the differing needs of countries globally, and to pilot and validate it in differing countries in two continents. Though the piloting, and the development of the educational and testing frameworks and systems, was grounded on the needs of the individual countries involved, the resultant tools and products are likely to yield wider benefits and use by other countries wishing to follow suit.

As well as being a key contribution towards sustainable health informatics systems, this initiative also marks a policy development for the ECDL/ICDL Foundation. It began the development of the Health module as a global

concept with the help of a group of subject matter experts. However, it became clear that the application of Health informatics systems required a certification that was closely tailored to national requirements including patterns of practice, culture, language, and legislative frameworks. As a result the ECDL Foundation adopted a modem of product endorsement. The core syllabus for the Health supplement is specified by the Foundation, but individual national license holders propose the format in which the national certification is developed and assessed within a specific country, ensuring this has local relevance. Each national certification is then endorsed by the ECDL Foundation. The Health certification is thus tailored to each individual country's health system. It not only uses the languages of the country, but the terminologies and taxonomies for health care practice, as well as professional and legal codes. The ECDL/ICDL Health Supplement is the first successful implementation of this Endorsed Product concept.

Conclusion

With the increasing importance of health informatics systems, and the need to ensure their effective and safe usage, there has been a steady and increasing recognition of the importance of end user competence as a contribution to effective sustainable implementation and development of such systems. Moreover, given that the issues and risks are basically generic, coupled with increasing mobility of health staff, the advantage of devising a generic solution has become self evident. From this position, the progress in the last two years through an expert committee identifying and confirming the core syllabus, and three different countries undertaking trials and detailed implementation plans, is significant and encouraging.

Like motorcars, aeroplanes, or other items of advanced technology, health informatics systems are only as good as the competence (and confidence) of their users. Hitherto this has gone largely unnoticed, except for possible training in a particular system's operational instructions. The ECDL/ICDL Health Supplement has broken new ground, by recognising the high importance of the education and empowerment of the end user, whatever their level or profession. It thus makes a vital contribution to the sustainability of health informatics systems.

Moreover, this is a global solution, linking common generic requirements with local need through the ECDL Endorsed Product concept. Having been developed by an international expert group, endorsed by the ECDL/ICDL Foundation, and now validated simultaneously in three very different countries, this product is now available for use in any nation.

Abstract

Many existing training programs for Health Information Systems (HIS) do not adequately satisfy end users' needs nor meet training objectives. This is because they do not envisage the problems that users may encounter when performing specific tasks. Therefore the first priority for the development of an effective training program is to precisely assess the end users' training needs, a process called Training Needs Assessment (TNA). Applying traditional approaches for TNA, such as interviews or surveys alone, however, may be insufficient because they are limited in their capacity to reveal the cognitive processes of end users. Usability testing, with its ability to gather data about human computer interaction, overcomes the deficiencies of these traditional approaches. This paper proposes a multi-method approach, which combines usability testing together with traditional methods, such as interviews or questionnaire surveys to assess HIS end users' training needs. This innovative method is able to precisely reveal the training needs for different levels of HIS users. A case study, which applied this method to assess the training needs for users of a nursing information system demonstrates its feasibility.

Keywords:

health information systems, end users, training needs assessment, usability testing

Introduction

A well designed Health Information System (HIS) can not only save staff time in entering and retrieving client data, but can also increase the accuracy and completeness of such data. The adoption of HISs, however, is not common in the current Australian healthcare sector [1, 2]. One of the reasons is that shifting from the traditional paper-based documentation to electronic documentation requires the users of an HIS to have basic computer skills, to be familiar with the HIS, and to change their practices of information management [3]. Managers are more and more aware that end user training is an essential strategy to accomplish this [4, 5] and that the failure to implement appropriate end user training strategy will leave staff feeling frustrated and threatened by the new system [6]. In the worst case, they may even reject the new system or resign, which in turn will lead to loss of organizational resources like skilled healthcare workers. It is important, therefore, that significant investment be made into end user training and support in order to ensure that the introduced HIS will be accepted and used by the healthcare workers.

An effective end user training program should have the capacity to deliver a timely, effective, efficient and enjoyable learning experience to the end users [4, 7]. In other words, it plays the role of closing the gap between the complexity of an HIS and the users' cognitive capacity to master it. The majority of existing training programs, however, are not as effective as they promise [8, 9]. The most common problems of these training programs are that they are ill-directed and inadequately focused [10]. For example, some training programs provide healthcare professionals with huge amounts of unnecessary information because they have been developed as a "one size fits all" solution [8, 9]. The fundamental flaw is that training needs assessment, namely, the process of assessing the training objectives [11], is not properly conducted for these programs so the training program designer can not accurately envisage the problems end users may encounter when performing specific tasks using the HIS. Thorough TNA is required to improve end users' learning outcomes and to enable them to become familiar with a new HIS efficiently.

In order to conduct a thorough and accurate TNA, the method of analysis should be scientifically designed, and this is the topic to be discussed in this paper. Firstly this paper will critique the traditional methods for TNA. Afterwards it will propose a novel method for TNA, followed by a case study demonstrating how to integrate the new approach with traditional methods.

Need for new approach in training needs assessment

The primary purpose of a TNA is to identify what knowledge and skills end users should have in order to enable them to effectively interact with an HIS. Through identifying the usage problems, the gap between the necessary and the actual knowledge and skills that a user has for effectively interacting with this IS can be inferred [12]. In other words, experimental Human Computer Interaction (HCI) data such as usage problems, mistakes or inefficient behaviors, are effective indicators of what they do not

know [13], which, in turn, suggests what they need to know. Traditional methods of TNA, however, lack the ability to collect such detailed information about the cognitive process end users follow in their interaction with a new IS.

The common methods of assessing computer users' training needs are self-reported questionnaire surveys and interviews with end-users [13-15]. Questionnaire surveys have a number of distinct advantages, including the ease of distributing questionnaires to a large number of users and the automated analysis of the results with statistical packages. The typical process of quantitative assessment consists of managers setting the required level of skills for a particular task, then a staff member is requested to rate his/her skill level against this standard [16]. A comparison between these two sets of data suggests this staff member's skill gap in accomplishing the task, however, this method can only identify difficulties of which the designers or skilled external consultants are already aware [15]. It can not detect all the challenges or mistakes that a user may face or make in using a particular HIS.

Similar problems underlie other commonly used methods like interviews or focus group discussion, where end users are asked to reflect on their prior experience with an IS. Such qualitative assessments provide opportunities for users to express their perceived difficulties in using an IS but these conventional methods are not adequate to assess the learning needs of users, particularly for users with different levels of experience with the system. For example, novice users may not have sufficient knowledge about this new IS to enable them to realize the problems they may encounter in using it [17, 18]. Even experienced users may not be able to clearly recall their problems [19]. Verbalizing the process that a person follows to complete a task is also problematic, as it involves the expression of sequences of psychomotor movement in interaction with an HIS [20]. In addition, users' perceptions of the same problem may be different because of differences in their educational or technical levels [21].

Thus the use of traditional TNA methods alone may not reveal detailed information about the cognitive process end users follow in their interaction with a new IS [21, 22] so data gathered from these methods are not adequate to identify end users' training needs. In other words, basing the selection of training strategy on the analysis of such incomplete data may lead to ineffective programs because there is a significant gap between what is perceived to be a problem and the actual problems that a user encounters. Traditional methods for TNA need to be complemented by more effective new approaches. Careful observation of how users encounter and react to problems in interacting with a particular HIS is necessary. The next section will explain our proposed methods and suggest strategies for dealing with the problems discussed above.

Cognitive usability testing method

There is a growing role for the cognitive and behavioral sciences in health informatics, particularly as it pertains to human factors, and other areas such as information retrieval and educational research [22, 23]. From the perspective of informatics, cognitive science can provide a framework for the analysis and modeling of complex human performance in IS [23]. Theories and methods from the cognitive sciences can illuminate different facets of the design and implementation of IS [22, 23]. They can also play an important role in understanding and enhancing human performance on a wide range of tasks. These tasks may include developing training programs to reduce errors and increase efficiency for healthcare [23].

Usability testing encompasses a range of methods for identifying how users actually interact with a complete software product. Empirical testing is a form of usability inspection that observes actual user interactions with an interface (Neilson, 1994). Given that many HISs fail due to usability problems, organizations are starting to show interest in usability testing. Some preliminary studies have been performed testing clinical information systems. For example, Kushniruk [24] introduces a laboratory-based usability testing method to evaluate the effectiveness of HISs. According to Kushniruk [24], usability testing refers to "the evaluation of an IS that involves testing of participants who are *representative* of the target user population, as they perform *representative* tasks using an IS". During the testing, all interactions a user has with an IS are recorded (e.g. video recordings made of all computer screens or user activities and actions). In addition, this technique generally includes the collection of "think aloud" reports, involving the recording of users as they verbalize their thoughts while performing particular tasks [24].

In brief, this approach focuses on classifying users' cognitive ability and then identifying the problems they encounter during their interaction with the IS. With its ability to gather rich empirical HCI data, this method provides an excellent opportunity to complement the weaknesses of interviews or questionnaires for assessing training needs. Although this method was originally designed for testing the usability of an IS, it is also useful for identifying training needs. In the early '90s, Simpson proposed a framework to describe how testing methods could be used in the planning phase of designing online documents [25]. A recent case study has used novice users' interaction with a search engine to reveal the knowledge and skills that such users need [18]. Our preliminary study which employed the usability testing method to assess the training needs of nursing students also demonstrates the feasibility of this method [26].

A multi-method approach for training needs assessment

We have demonstrated the viability of cognitive usability testing methods in capturing process data on how an end user interacts with a particular IS. We propose that a multi-method approach combining usability testing with conventional methods like interview or questionnaires can precisely and thoroughly understand the process end users follow in processing information in a particular HIS. It can also suggest the knowledge and skills that these users need to learn in order to use the HIS.

The process of our proposed approach is to:

- observe how novice, intermediate and veteran users use an HIS to complete representative tasks.
- interview or survey these users before or after conducting cognitive usability testing, in order to ascertain their level of the knowledge and skills that are relevant to the HIS that they are trained to use
- extract patterns of strategies used by the novice, intermediate and veteran users to complete various tasks with this HIS.
- identify the key knowledge gaps (learning needs) of different levels of learners based on the different interaction patterns that they display when using the HIS.

In the following sections we describe three approaches which can be utilized for an innovative TNA.

Usability testing approach

The following three issues need to be considered when performing usability testing.

Participants

Participants for the experiment are potential or actual end users. Based on their experiences with the HIS (e.g. measured by the time and frequency of their usage of the system), they can be categorized as novice, intermediate, and experienced users. The recommended sample size varies between usability experts. As Nielsen and Mack suggest [27], usability testing can be carried out using only five participants, and the results will demonstrate 85% of the usability problems. Kushniruk *et al.* [21] suggest that up to 80% of usage problems can be detected from 8 to12 participants evaluating a system.

Outcome measurement

Kushniruk *et al.* [21] suggest that the usability testing should involve setting up recording equipment that allows for continuous recording of computer screens during the process of human-computer interaction. To achieve this goal, Camtasia Studio, screen recording software, can be used to record each participant's mouse movement and keyboard strokes. In addition, participants' "think aloud" reports can be audio-taped. The data analyzed for usability analysis included both the video and the audio file.

Data analysis technique

Prior to analyzing the video data, a coding scheme should be defined for use in identifying specific occurrences of users' problems and aspects of cognitive processes from transcripts of a participant's "think aloud" comments. A coding taxonomy developed by Kushniruk can be used for analyzing human computer interaction data [22, 24].

- Navigation: used when participants comment that they are navigating, or indicate that they are incapable of moving through the interface to find the relevant information or accomplish what they are supposed to do.
- Understanding: used when participants comment on understanding the meaning of labels, instructions or errors.
- Ease of use: used when participants comment on the level of "ease of use" of the system (from easy to hard) or any confusion or frustration experienced.

A case study

The NIS described in this case was the Care Planning Assessment Tool (CPAT), owned by the Hammond Care Group. The CPAT was introduced to help nurses carry out systematic assessments for nursing home residents. The "Clients" menu enables users to perform the most crucial functions of the CPAT, i.e., doing data entry and assessments for clients (i.e. residents), see Fig 1 for a screen shot of the assessment screen. In the assessment screen, users can enter detailed assessment results for a resident. The program can then generate various assessment related reports.

This particular study aimed to assess the training needs for different levels of the CPAT users, so as to develop the "right" training materials for the "right" groups of users. The training materials for the CPAT are:

- User Manual: this is usually for novice or first time users and should be very detailed.
- Online Help: this type of training is traditionally for the relatively experienced users who require help while using the product; it usually contains information on how to conduct a task.

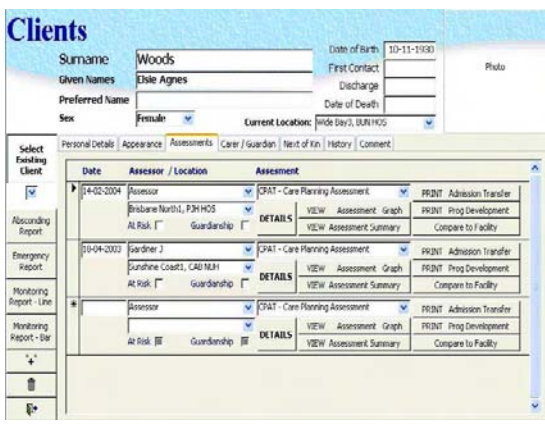

Fig 1 - The assessment screen of the CPAT

Procedure

Based on users' knowledge and experience with the CPAT, they are classified into two categories: novice and experienced users. The process of the training needs assessment in this case study was to:

- conduct laboratory-based usability testing to observe how novice CPAT users complete a series of data entry tasks using the CPAT;
- interview a cohort of experienced CPAT users to understand the problems they often encounter in using the CPAT software
- analyze two sets of data to identify knowledge gaps;

- integrate the findings into the design of training materials.

Usability testing experiment

Eight participants for the experiment were recruited from third-year nursing undergraduate students from the University of Wollongong. All the participants majored in geriatrics. They were potential users of the CPAT but had no previous usage experience with the software.

The participants were asked to perform the following three representative tasks supported by the software:

- entering data for a resident;
- doing an assessment for a resident;
- generating a change monitoring report.

The participants were encouraged to "think aloud" or verbalize their thoughts if they were uncertain about how to conduct the above documentation tasks using the software.

Findings

There were eight video and audio data collected from the experiment. Analyzing the triangulation of audio and video data identifies a series of problems that novice CPAT users encountered in this training session. An excerpt of a coded section of such triangulation is given below to show how users' interaction with the software was coded.

> 20:40 – user finished scoring "communication problems" and intended to answer the next group of assessment questions.
>
> "How should I go to the next group of questions?"
>
> *Navigation - having problems navigating between assessment criteria.*

By coding all of the participants' usage problems, three groups of problems that users encountered were identified:

- basic computer skills, e.g., users do not recognize the drop-down icon in the selection fields.
- knowledge about the software, e.g., users do not know where to score questions about assessment criteria
- domain knowledge about nursing documentation, e.g., users do not understand some assessment questions

Focus group discussion

A semi-structured focus group discussion involving nine veteran users from the Hammond Care Group was conducted to explore their learning and work experience with the CPAT. The participants were the actual users of the CPAT. Their roles included facility manager, trainer, consultant and dementia care worker. Most of them have more than three year's CPAT usage experience.

Participants were prompted to provide their answers for the following questions:

- How did you learn to use the CPAT?
- Could you recall any problems encountered when using the CPAT?
- What kind of help do you expect when you encounter problems?

Findings from the focus group discussion

The normal method of learning the CPAT was labor-intensive, one-on-one coaching, followed by self-directed practice. If the user encountered any problems, they could either approach the trainer or try to solve the problem by themselves. A list of frequent usage problems was identified through focus group discussion. It ranged from system-related problems to computer-related problems.

Discussion

The findings from the TNA identified both procedural and conceptual usage problems in the format of HCI (usability testing) and verbal expression (focus group), which provided valuable input into the design of both the user manual and online help for the CPAT software. For the user manual, usability testing vividly revealed three types of novice-user knowledge gaps, which would become the main focus of the user manual. In addition, frequently asked questions gathered from focus group discussion can be effective contents in the user manual as these problems are also common for novice users. For the online help, problems that were identified in usability testing and were summarized in focus group became the core contents of online documentations. In addition, feedback from experienced users suggested that the learners like functions like video demonstrations. Therefore, this new approach for TNA has proved its capacity to precisely and thoroughly identify the training objectives for both novice and experienced users.

Conclusion

In this paper we have firstly presented the strengths and weakness of a number of traditional methods (interviews and questionnaires) that are used for TNA for novice users of an HIS. Next we described the capacity of cognitive usability testing to capture the cognitive process of HIS users in their interaction with the system. We argue that using the conventional methods alone has limitations and that they could be complemented through combining cognitive usability testing with the conventional methods. This proposed new approach has been explained in detail, particularly through demonstration of a case study, which involved assessing the training needs for users of a nursing information system through two approaches: cognitive usability testing and focus group discussion.

Acknowledgement

We would like to acknowledge the contributions by:

All the participants in the laboratory and focus group.

Mr. Richard Fleming, owner of the CPAT application, for his support in providing introduction to the CPAT software for the participants of this experiment.

Dr. Patrick Crooks and Ms. Joanne Joyce and staff in Nursing school in University of Wollongong for encouraging and recruiting their students to participate in the experiment.

Dr. Madeleine Cincotta, for her generous help in editing and proof-reading the final manuscript.

Making Health Informatics Competencies Useful: An Applied Health Informatics Competency Self-Assessment System

H.D. Covvey, S. Fenton, D. Mulholland, K. Young, B.A.E.

Waterloo Institute for Health Informatics Research, University of Waterloo, Waterloo, Ontario, Canada

Abstract

Years ago we undertook to define Health Informatics (HI) competencies. This effort resulted in the creation of a document that articulated HI roles, the challenges faced by HI professionals, the high-level tasks that they needed to undertake to address these challenges and the competencies (skills, knowledge, and experience) they needed to complete these tasks. Unfortunately, in so doing we created what is arguably the most boring book in history, shoes contents are very difficult to extract, use, maintain and improve. We report here the completion of a pilot of a system that we believe corrects this situation. It is a web-based tool that incorporates all of the material, from roles to detailed competencies, enabling them to be accessed and used for a variety of purposes, the most notable of which is professional self-assessment.

Keywords:

health informatics education, competency assessment

Introduction

Canada Health Infoway and other Canadian organizations involved in the deployment of ehealth infrastructure have pointed out that they face major challenges in accessing human resources with Health Informatics backgrounds. There have been estimates that as many as 2,000 positions in Canada go unfilled or are filled by less-than-fully qualified individuals.

Canada already has university and community college-based programs in HI, but these produce less than a hundred HI professionals per year. Even with a number of new education programs emerging, there is little hope of increasing this number significantly over the next 3-5 years.

In addition to this, the reality is that few students in our high schools or many of our post-secondary institutions have even heard of opportunities for careers in HI, or even what HI is!

This lack of awareness was echoed by academic experts and industry leaders from Canada, United States and Britain at the eHealth Conference 2005 in Toronto, Ontario who called for aggressive action to resolve the health informatics human resources gap. Rapid education deployment programs like AMIA's 10 x 10 program and the Waterloo Institute for Health Informatics Research Boot-camp program have been launched as attempts to correct this situation. However, there is still minimal awareness of the nature of HI, the roles that HI professionals perform, the education required to play a role in this field, and the opportunities for employment for graduates.

Moreover, many health-related public and private sector organizations that would benefit from HI expertise are only just becoming aware of the competencies required of health informaticians, or that education and training is available in our universities and colleges. One consequence is that recruitments are not properly informed regarding required competencies, when candidates are found, poor choices can easily be made in hiring.

The field of Applied Health Informatics (AHI), that most relevant to health organizations and the vendors that serve them, blends the informatics and health disciplines to find and deploy the best possible technical solutions to a wide range of healthcare information-related challenges. Thus, people in AHI need to have a solid technical background, a detailed knowledge of the healthcare industry and of the capabilities it has produced, and a wide range of personal, organizational and cultural, business, managerial and analytical skills.

AHI self-assessment system

We undertook several years ago to address the need for Health Informatics career awareness in part by beginning the development of a unique and innovative web-based Health Informatics competency self-assessment tool. This tool helps students, potential students, and the individuals who want to hire them: (1) to understand the types of roles that exist for individuals trained in Applied Health Informatics, (2) to understand the competencies required to fill these roles, (3) to self-assess their (or their candidate's) knowledge and skills against the competencies required in these AHI roles, (4) to take objective tests to validate their perceptions of their competencies and (5) to find educational resources that enable them to address deficiencies that are identified.

The primary purpose of this tool is to serve as a self-assessment system and to provide an index to learning resources. It is intended as a resource for students, teachers and employers related to understanding the skills, knowledge and experience expected of competent Applied Health

Informaticians. Furthermore, the competencies and competency categories embodied in the tool and supporting documentation[1] can assist curriculum developers in defining the educational content for Applied Health Informatics education programs. The system is also intended to be able to serve as a "front-end" or entry point to an educational program that can be used to document progress related to the competencies the student needs and has acquired.

It should be noted that our framework to define competencies and the tool we built to support self-assessment and access to learning resources are entirely general and can be applied to any discipline, not just to Health Informatics. This makes our framework and tool reusable and of broad potential interest.

Methodology

In earlier work [1], we led a process that defined HI competencies and supporting curricula using a team of approximately 100 health and Health Informatics professionals (including HI teachers/researchers, curriculum developers, human resources professionals in healthcare organizations and HI companies, vendor staff, government representatives, and current and candidate students). This work involved the comprehensive documentation of HI roles, the challenges faced by professionals in each of these roles, the high-level tasks (which we called "micro-roles") that professionals in these roles need to undertake to address the challenges, and the competencies required to accomplish the tasks/micro-roles [1,2]. This material was then used to define content that could be used as the basis for a number of programs world-wide [3]. One such program has been established at Conestoga College, in Kitchener, Waterloo, Ontario, which registered its first students in the fall of 2005. The competency definition project was funded by the Canadian Institutes for Health Research (CIHR), its products are frequently cited, and today it stands as one of the few definitions of HI competence that have been derived using a logical framework (a work breakdown structure) rather than being solely based on the preferences and opinions of teachers with their own programs.

Once having completed the documentation of competencies (there are on the order of 400 for AHI alone) and the other components of this project, we recognized that the form they were in needed to change. In particular, they were incredibly boring to read, making improving them an un-motivating task. In 2001, F. Lau at the University of Victoria made the suggestion that we consider some way of encapsulating or packaging the competencies and other content in a directly usable form. We considered this suggestion and realized that significant value could be derived by packaging the competencies in a software tool that made them accessible, available and integrated for review, understandable, and actually usable by individuals in the field.

We called this tool "WebSAT" and built it using the Web-based Informatics Development Environment (WIDE) developed by the Computer Systems Group at the University of Waterloo, led by D. Cowan [4]. WIDE is intended as a rapid pilot system definition environment, based on a decade of Software Engineering research, composed of software services and are customized using declarative techniques. The goal of WIDE is to reduce technological barriers to system design and development.

WIDE is primarily based on open source software technology and consists of a number of services and supporting frameworks. Applications can include input forms or reports containing extensive multimedia materials such as imaginative use of maps or any 2-dimensional diagram, websites, databases, indexing and searching methods, agents, and push technologies. WIDE also contains a knowledge management system that supports documentation of technical information and best practices. The structures underlying the services are usually expressed in an XML-based declarative language that uses metadata and XSL. In the WIDE metadata context, "programming" has effectively been replaced with a declarative methodology thus making it possible to provide a wizard or forms-based approach to building Web-based systems. Internally WIDE uses a bootstrap approach; its extensions are implemented using its own metadata technology. WIDE can support a rapid development paradigm and new applications can be quickly built and demonstrated. The components of WIDE are described next.

A mapping services framework. Interactive maps are delivered from a map-server, which supports zoom-in or zoom-out functionality and positioning over areas of interest. When connected to a database or other directory the maps can be used to display and interact with the location of a geo-referenced object. Map searches can be defined by a circle, or general polygon. The mapping service framework does not use traditional GIS software.

A diagram and chart services framework. This framework manages and delivers specified interactive diagram and chart types upon request for presentation of data on the Web or in other formats. The diagram and chart services are also based on the Scalable Vector Graphics (SVG) open W3C standard and so provide similar functionality to the mapping service framework.

An XML-based metadata framework. The structure of databases, websites, agents, and applications including reports and input forms with maps and diagrams are described using XML. They are transformed into operating applications through the use of XSL "programs." Any application can describe and subsequently access databases or Web sites reachable anywhere over the Internet.

A report services framework. This framework supports the management of interactive report and input form types including maps, charts and diagrams and delivers them on request for presentation on the Web or in other formats. The user indirectly specifies the form type and the data that that is to be presented or requested; the framework chooses the report or input form type and populates it with the requested data.

A content management services framework. This framework supports the management of text and multimedia information in a database where it can be viewed, searched, maintained and then published for use on the Web or in other formats.

An access control service framework. Access to any content such as a database, website or other text and multimedia content can be provided with multi-level access controls to determine who can read or change data.

A Web and database searching service framework. This service framework contains an indexing agent and search engine that will index known websites and databases and support searching. The results from Web searches are categorized based on different search criteria such as the proximity of words in a phrase. The results of combined database and Web searches can be presented together. The results of the two searches can be compared to see if new results have appeared in the intervening time interval.

A push/notification service framework. The general push/notification service framework allows developers to create systems that allow users to specify conditions under which they wish to be notified or have information pushed at them.

An agent service framework. The agent service framework supports the description of agents that will act autonomously to perform utility tasks within an application. Agents are often defined to manage redundancy. For example, agents could be defined to verify the content of "local" databases against authoritative sources or to allow a user to type information once while submitting the data to multiple databases or Web sites.

The academy – a knowledge management framework. The academy framework is used to support widespread dissemination of "documentation" and knowledge describing how applications can be built from the WIDE Toolkit.

Description of WebSAT

WebSAT (Web-based Self-Assessment Tool) is a Web-based AHI self-assessment system that enables individuals to review HI competencies, assess their own competencies and compare these to the competencies required for specific roles. The development of this system was funded using internal resources and volunteer labor and is now available as a demonstration website on request to the author. In return, we ask users to complete a brief assessment of the system for us.

Our competency definition work identified three types of HI professionals: (1) AHI (Applied Health Informatics) professionals, who define the requirements for, procure, deploy, implement, manage, guide the use of, and evaluate HI systems and methods in health enterprises and their supporting industries; (2) RDHI (Research and Development HI) professionals, who teach, do research, and develop innovative HI tools for the health system and are typically found in academia and private industry research labs; and (3) clinicians who need HI competencies to be good clinicians (called Clinician HI or CHI).

In order to make the initial version of the system of manageable scope, we limited ourselves to providing a tool for those interested in assessing their own competencies relative to those required by AHI professionals. Furthermore, we did not address many of the user interface issues. For example, we did not allow individuals to assess themselves first at a high-level (versus broad categories of competencies) and then at a more granular level within these categories.

This past year we extended the development of this tool through the able assistance of a student working in the Undergraduate Research Assistant (URA) program in the David Cheriton School of Computer Science (D. Chodos). This student added references to Web-based educational materials for sample set of competencies. This allows users to click on a link and access educational documents, on-line educational programs, and on-site courses that provide a means to correct competence deficiencies. This has turned out to be an excellent capability that supports lifelong learning in this field. This latter work was reported at the recent eHealth 2005 Conference in Toronto [5].

During the last 6 months we have made major improvements to the system:

- A new user interface has been developed that makes use of the system more intuitive.
- Users can now assess themselves at a high-level (compared to competency categories) or at a detailed level, reducing the effort if the user does not need to go to a deeper level.
- Improved graphics show the comparison of the user's stated competencies to those required by the selected role.
- There is a new query capability that allows recruiters to retrieve the competencies required for various roles, based on the importance of the competencies.
- The system supports the self-assessment of experience.
- A capability to take objective tests is now included so users can validate there perceptions of their competencies.

Finally, the overall system now has a better look and feel to improve the user experience.

Mode of operation

WebSAT operates as follows:

- Users who access the system are asked to register under a user identity and password that they create.
- The user can review the definitions and detail of any of the components used to define competencies, including possible roles, challenges, skills, etc. This is the part of the system that supports the understanding of AHI itself and the review of details that the content developer may add, delete or improve.
- The user can then select one of the potential AHI roles, after reviewing descriptions of each role. The users stated competencies will be compared with this role (this can be changed at any time).

- The user can then access approximately 20 "competency categories" (groups of similar competencies), each containing multiple specific competencies, and can assess him/herself as to the level of knowledge or skill he/she has. Competencies are assessable as one of seven levels from "no knowledge" to "expert"). These levels include: UNA=Unacquainted; ACQ=Acquainted; PAM=Passing Familiarity; GAM=General Familiarity; FAM= Working Familiarity; CAP=Capable; EXP=Expert)
- If the user wishes, she/he can drill down to detailed competencies within the competency categories.
- The system allows corrections and the saving of input for later completion.
- Once the user has responded to all competencies at whatever level of detail desired, the system compares the user's competencies to the selected role and provides graphical feedback (a bar chart of responses versus requirements) as well as textual feedback. Different roles can be tried, to see if there is a better fit with these.
- For areas requiring further work, the users have the opportunity to receive system guidance to educational resources.
- Users can access objective tests for each competency.

The competency categories included in the system are:

1. Personal Competencies for AHI
2. General Computing Competencies
3. Health Computing for AHI Professionals
4. Key IT Usage for AHI Professionals
5. General Health System Competencies
6. General Business/Management
7. General IS Department Management
8. Team and Human Resources Management
9. Re-Engineering and Management of Change
10. Strategic and Operational Planning
11. Assessment of the Value, Effects, and Cost of IT
12. General Technology/Systems Life-Cycle Management Competencies
13. Procurement Competencies
14. Systems Implementation and Integration
15. Systems Maintenance and Support System Customization/Ad Hoc Development
16. Project Management Competencies
17. Education and Training Competencies
18. Vendor/Service Provider Competencies
19. User and Process Observation and Assessment Competencies
20. Security Management Competencies
21. Information and Data Collection, Analysis and Management Competencies

A total of approximately 400 separate competencies allocated under these categories are addressed by the system.

Results

WebSAT has now been tested by both by graduate students in our HI program and by students in a new HI program at a nearby community college.

Students have reported a high degree of satisfaction with the system. They found the system useful and informative, and it gave them a clear view of what they still need to learn and where they stand relative to the requirements of various roles.

We have recognized, however, that other improvements are possible, and we continue to enhance the system further along the following lines:

1. We are undertaking further improvements to its user interface so that it can be more efficiently used by inexperienced users.
2. We are completing the addition of learning links to Web-based educational sources to be referenced by students with identified weaknesses.
3. We are adding additional objective tests and creating a new testing engine. The existing one does not support sufficiently complex multiple choice options.
4. We will extend the tool to incorporate Research and Development HI (academic-level) self-assessment to the same degree as the AHI assessment.
5. We are in the process of offering the system to other programs for use as a tool for students, and we are seeking recruiters to test its support for their activities.

Summary and Conclusions

We have developed a Web-based competency self- assessment system for Applied Health Informatics. This system allows individuals to assess themselves as to the congruence of their competencies with those required for specific roles. The system has been tested on students and is in the process of being enhanced and disseminated. Individuals interested in accessing the system personally or using it as a component of their programs are invited to contact the first author. The system is offered without charge.

Acknowledgements

This work was supported by NSERC under the Executive Industrial Research Chair program and by Canarie Inc. The authors are grateful for the contributions of D. Chodos, research assistant, at the University of Waterloo. The authors are grateful to F. Lau at the University of Victoria who first suggested the development of this system.

Abstract

A local study carried out in the Medical School of Grenoble shows that teaching in the first year in medicine studies satisfies neither the students, nor the teachers. The Faculty of Medicine of Grenoble decided to set up a reform in order to offer a high quality education. This reform leads to a complete reorganization of the curriculum and to the intensive use of new information and communication technologies of information, in particular, the use of multimedia documents. The communication and information technologies team of the Faculty of Medicine of Grenoble carried out an innovating and daring reform to start at the academic year 2006-2007. The new course is built on three activities: self learning on multi-media resources, meetings with teachers for questions-answers sessions and tutorials animated by older students. This article reports the first results for this successful project. In the academic year 2006-2007, are concerned 1290 students, 40 teachers and 8 disciplines.

Keywords:

e-learning; first year medical curriculum; multi-media; Grenoble, France.

Introduction

Observed difficulties during the first-year curriculum

A degradation of working conditions

This degradation was explained as a consequence of years of teaching without innovations or improvements. From a teaching point of view, the acquisition and transfer of knowledge remain extremely antiquated. The majority of learners remain passive. The student remains isolated before a task that cannot be managed without help. This may generate harmful consequences on his learning capacity..

A regular increase in the number of students

The increasing number of students is a factor which amplifies the degradation of the working conditions. Since 1975 the number of admission in second year has dramatically increased. The "numerus clausus" of Grenoble corresponds today to 12% of the number of registered students (year 2006, 1300 registered students against 166 students allowed to continue the second year course). The amphitheaters have a normal capacity of 650 places whilst 800 students actually attend the lectures. This number cannot possibly be increased for safety reasons.

A contest which no longer fulfils its role

The contest no longer fulfils its double role of regulating the number of students and selecting the best ones. Studies showed that the harder a contest is, the less effective the selection of the best students is. This strong selection has many direct and indirect consequences such as some influence on the content of the lessons. Difficult lessons only exist for their selective character and not for their relevance.

Inadmissible behaviours

The extremely selective aspect of the contest has generated an attitude of unfair competition behaviour, such as voluntary disturbance during the lectures by a few students, voluntary locking of the books to limit there availability, paper planes sent through the amphitheatres, going to the extreme: sale of already annotated lectures showing voluntarily added errors. These behaviours go against the university values of solidarity and equity amongst students.

Less equity between the students

Many a student registers in private courses which offer method and regularity in work in order to make up for the effects of these bad working conditions. This is also a means for the getting of annals and self assessment in relation to others. In the French system, the inscription to these courses generates a discrimination against money since the first access price exceeds 1500 € .

Effects over the forthcoming years

One of the indirect but considerable effects of this situation is that the motivation to work is getting slack. This is understandable considering the very great efforts provided for during the first year. Teachers estimate that students need three years to come back to a normal working attitude.

Solutions already tested by other universities were not very conclusive

Faculties of Medicine, facing the same difficulties, and drawing the same conclusions adopted various solutions:

- One of them is the repetition of the courses, which obliges the teachers to reproduce at various gaps the same course in many amphitheatres. That demands a great involvement from the teachers and availability of many extra amphitheatres (with a capacity exceeding 700 places). The risk is this might encourage the action of disturbing students, increase the loss of interaction between teacher and students and generate problems with regards to safety. For all of these reasons, this solution cannot be applied in all Faculties.
- Another very widespread solution adopted by various Faculties is the broadcasting of the course by Video-transmission in a secondary amphitheatre. The principle consists in diffusing on line and on large screen in a secondary amphitheatre the course done by the teacher lecturing in the first amphitheatre. This reduces the number of mobilized teachers. However, to be added further to the already listed problems, the high costs for expensive, fragile and not always reliable equipment which cause considerable discontent among students. Answering the student's questions is difficult and this increases the risk of disturbance.

The need for an important reform

Whatever the solutions considered by the universities, the quality of the teaching is unfortunately not improved, on the contrary it is damaged. To face the whole of these drawbacks, the Faculty of Grenoble team has proposed a reform which leads to an original solution.

Materials and methods

Elaboration of an original reform

Emergence of the project of a reform for the first year medical curriculum, all the actors at the medical school carried out a complete thinking on the modernization of teaching. Administrative people (Dean...), teachers, and students (elected representatives) endeavoured to find a solution which would improve the quality of the teaching. In there analyse, they took into consideration different dimension like behaviours [1,2], cognitive sciences [3,4] and possibilities offered by the communication and information technologies [5,6]. A reform combining a new organization of teaching associated with an intensive use of communication and information technologies appear to be the best alternative.

Specificities of the medical profession

Given the teacher's specific statute, the Faculty of Medicine offers more freedom. Most teachers of Medical School are not subject to a quota of hours before the students. A modification in manner of delivering of the courses will not be a problem due to their teacher statute.

Grenoble specificities

This project is in the continuity of previous reforms made for the years following the fourth year (2002-2003), and for the years between the second and the third year (2003-2004) of the medical curriculum. Another particularity is the strong motivation of all the teams involved in teaching for an intensive use of new communication and information technologies.

New methods of training

The reform does not change either the curriculum program or the organization of the contest.

The year (2006-2007) is divided into 2 six-month study periods. Each semester ends with a part of a contest (January and May 2007). One six-month period is divided into 12 training sequences, each sequence divided into 4 weeks.
Each week is devoted to a different training activity.

- The first week is devoted to the study of the courses on DVD-Rom: one or two different disciplines are studied over the week in the form of multi-media courses animated and wired for sound by the teacher's commentary.
- The second week is used for the formulation of all questions destined to teachers. These questions exclusively relate to the multi-media courses studied during the previous week. They are the base of the Question/Answer Meetings. The questions are formulated on the Faculty of Medicine of Grenoble's web site which is destined to the PCEM1 students (www.medatice-grenoble.fr). The on-line form is open each week, from Saturday to Tuesday exclusively. The access is secured by a login-password provided for at the time of final registration.
- The third week is devoted to the Question-Answer Meetings. Each discipline studied during the sequence is followed by a 2 hour Question/Answer Meeting. These meetings are held in small amphitheatres. Students are divided into eight groups. The meetings are ensured by the teachers in charge of the discipline. The answers are built from the questions collected on the on-line form (www.medatice-grenoble.fr).
- The fourth week is dedicated to the tutorials. The tutorials are directed by third year tutor medicine student. These meetings are intended for QCMs training. QCMs are validated by the teachers, corrected and explained during the meeting by the tutor students. These students are trained and supervised by the teachers in charge of the disciplines and the contest. The meetings are held the week following the questions-answer meeting.

Recording of the multi-media courses

Recordings are carried out by the Stendhal University Audio-Visual Service. The multimedia resources consist of animated slides commented and recorded by the teachers.

Evaluation of the reform

The evaluation of the project lies on statistical data describing the correct working of the project as well as on satisfaction surveys carried out weekly. At the end of each tutorial session, students are questioned. The information collected concerns the evaluation of the lesson and training methods.

Agenda for the project

The Table 1 reports the agenda for the project.

Table 1 - Agenda of the project

Date	Event
November 2005	Realization of the preliminary study
December 2005 to January 2006	Redaction of the performance specification
February 2006	Validation of the project by the Université Joseph Fourier's council
March 2006 to September 2006	Production of the multi-media records
July2006	Opening of the web designed for the students in their first year
August 2006	Production of the DVD-Rom number 1 (2000 pieces)
September 2006	start of the curriculum – distribution of the DVD-Rom N°1 to students

Results

Numbers of students and teachers

The teaching of the first year of the medical curriculum in Grenoble concerns 1290 students, 40 teachers and 8 disciplines for the year 2006-2007.

Self learning on DVD-ROM

There was 230 sessions corresponding to 460 hours of recordings. The slides are in flash-R, mp3 and xml format. The materials are equivalent to 220 hours of listening by the students.

Every six months, a new DVD-ROM is distributed to the students. The DVD-ROM contains 4, 7 Go of data (The mean size of one course is about 26Mo). DVD-ROMs are pressed in 2000 specimens. Each DVD-ROM cost 1,60 euro.

The courses are also available on the web site dedicated to students under the form of Podcast using Open source Xvid file format [7].

The user assistance for DVD-ROM usage only received 16 calls and all of them were solved by the assistance.

The hot-line was overloaded by calls coming from students registered in Universities other than Grenoble to get the DVD-ROM.

Students will fill an electronic form after each course. Every week 1050 students will fill the evaluation form. 36 000 forms will be delivered during the year.

The students' satisfaction rate ranges between 75% and 85%

Figure 1 – self-learning rich media

The questions-answers sessions

The students send their questions through an on-line form. The questions must be related to the courses delivered during the previous week and are collected from eight independent groups of students.

At the end of the first cycle (the first four weeks), 900 students have used the system and asked 7484 questions which were marked "pertinent" 38 879 times by other students. The satisfaction level for that system was 85%.

The session with teachers was organized in small amphitheatres. Every student followed two sessions per week. Each session lasts two hours The ratio questions-answers sessions over self-learning time is two hours of questions-answers for ten hours of self-learning time.

The number of questions per teacher varies between 200 and 300. The quality of the question is qualified as good by teachers. The satisfaction level of the student is between 55% and 75%.

Tutorial session

The 1290 students are divided into 40 small groups. Every student follows two sessions per week. Each session lasts two hours. 96 hours per student and per year are envisaged.

The tutors are older students (120 students in their third year of medical curriculum). A session is animated by two students (always the same two students). The two students are supervised by teachers and spend two hours for the preparation of a session which content is a set of QCM.

1 000 000 QCM are planned to be written over the year.

The mean satisfaction rate is 94%.

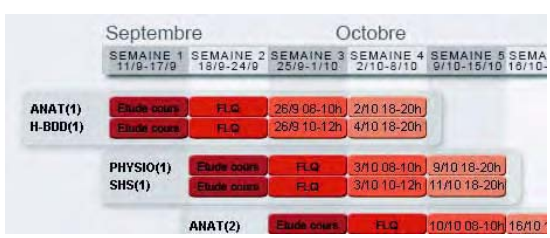

Figure 2 – The four activities of the learning cycle: self-learning on multimedia supports (Etude de cours), preparation of questions for teachers (FLQ), questions-answers session with teachers (ie 26/9 08h-10h) and tutorials (ie 2/10 18h-20h).

Logistics

A 700 places amphitheatre was converted into a multimedia room. It was adapted with 130 desktop computers, electrical connectors for personal laptop computers and with WIFI network connexion.

This room can accept 248 students who work in twos. It is open from 8h-20h and from Monday to Saturday

There is a low cost rental service for laptop computers and, in some cases, laptops can be lent.

Other rooms were adapted with computers and dedicated to questions-answers sessions as well as tutorials sessions.

During the first week, only 5 students used the 700 place amphitheatre. During the first month, the maximum number of students was 30.

The Web Site

It started in June 2006 and is reserved to first year students (www.medatice-grenoble.fr). It provides information on the organization of the curriculum. It gives access to the forms planned for their asking questions to the teachers. It is an entry point to access to the podcasts.

The average number of daily hits is 875 and the maximum 1200. In October, there has been 21 899 visits and 448 932 pages loaded.

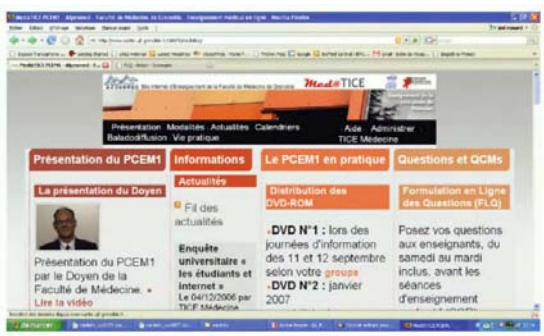

Figure 3 - The web site reserved to first year students

Discussion

The first result of satisfaction from students must be monitored to confirm the efficiency of this organization.

An element that needs to be confirmed is the uselessness of the multimedia amphitheatre.

A curriculum based on a four week cycle requires strong motivation from the teachers, how it will evolve in time is the question to ask.

The efficiency of a learning cycle lead on the sequence: self-learning on multi-média materials, questions-answers with teachers and tutorials with senior's student must be the subject for further analysis.

Conclusion

"The doctor of the 21th century must also have teaching competences in technologies which must be acquired at the time of his training" (Thierry KARSENTI).

The MedaTICE project showed that motivation and conviction of a team make it possible to carry out a joint and innovative project to it success.

Undoubtedly, the action taken by the Faculty of Medicine of Grenoble will be the starting point of a great scale disruption and will lead other faculties to become involved in similar projects.

It will be very important to follow on a monthly basis the statistics on the project and to do a complete analysis at the end of this first year.

[c] *Department of Informatics, Faculty of Medicine, Univ. of Porto, Portugal*

Abstract

The main objective of the Introduction to Medicine (IM) subject of the first year of the Medical Course at the Faculty of Medicine of the University of Porto is to provide students with a first contact with the areas of Biostatistics, Medical Informatics, Bioethics and the History of Medicine in the belief that they will be better prepared to learn, research, evaluate, share and decide within their practice. This paper presents a case study that describes how the subject IM is organized and how the b-learning tool (Moodle) is used to correct and grade the students' work. From the 239 students registered to attend the Introduction to Medicine subject 12% failed. The average grade among the successful students was 16 (out of 20). In the previous academic year only 2% of the students failed. However, among the successful students, the average grade was inferior (15 out of 20). The e-learning model that was described in this paper was successful because the results show that the students that made use of the Moodle got better grades.

Keywords:

education, medical faculty, e-learning

Introduction

The practice of Medicine requires the use of methods in order to acquire, store, process, analyse, transmit, evaluate and assess information as well as medical knowledge [1]. The study of scientific areas such as Biostatistics, Medical Informatics, Bioethics and the History of Medicine can contribute to improve the practice of Medicine and make it well supported by ethical principles and, therefore, socially effective. The main objective of the Introduction to Medicine subject of the first year of the Medical Course at the Faculty of Medicine of the University of Porto (FMUP) is to provide first year medical students with a first contact with the areas described above in the belief that, as future doctors, the students will be better prepared to learn, research, evaluate, share and decide within their practice [2]. Although there was some existing material on the Internet, it was only in October 1999 that an intranet for this subject was designed and implemented by the responsible professor and lecturers of the same subject [3]. The first interface, developed using PHP and HTML programming languages and a relational database, namely Postgres, in a LINUX server, was used to store and manage information. In the academic year of 2005/2006 an e-learning tool (i.e. Moodle) was introduced. This was done in order to use information systems' technology to provide for automatic students' work correction and evaluation.

This paper presents a case study that describes how the subject of Introduction to Medicine is organized and how the 'b-learning' tool is used to correct and grade the students' work in the academic year of 2005/2006.

Motivation for the use of an e-learning tool

A vast majority of first year Medical students are not interested in learning basic scientific subjects. They probably think that their content is not important for the clinical work ahead of them, and for which they have motivation. The introduction of technologies such as e-learning tools that bring new interactive methods for communication and simulation can help the lecturers to motivate the students and facilitate their learning process. Several case studies support the use of Web technologies in order to teach undergraduate Medical students [4].

Initial expectations

Although some of the material from previous academic years already included interactive means to communicate and learn (e.g. forums, chats, placard) the main objective to introduce Moodle was to use the specific module that allows students to make exercises and tests online, which are corrected automatically. With this module, the lecturers wanted the students and themselves to have a better understanding of the evolution of the students' learning results along the year with the main goal to improve the students' final results at the end of the year. This module eliminates the waiting time that was needed for the lecturers to correct the exercises and tests made by the students therefore simplifying the process of correcting and grading the weekly correction of 230 tests.

Objectives

The main objective of this case study was to create an e-learning platform that allows the students and lecturers to

follow the progress of students' work along the year. This helps the students to understand how they need to change or not their learning process with the real-time feedback they get.

Other objectives include facilitating students' access to the lectures' material as well as other interactive material and online communication means between students and lecturers that help and motivate the students to study and learn.

During the academic year, the lecturers noticed that the objectives were being achieved because the students were using regularly the material described above. This could be seen by consulting the usage statistics module within Moodle.

Materials and methods

Structure and grading system

Introduction to Medicine is a subject from the first year of the Medical Course of the Faculty of Medicine of the University of Porto that integrates four modules regarding the following scientific areas: Biostatistics, Medical Informatics [5], Bioethics and the History of Medicine. In the academic year of 2005/2006, 239 students were registered in order to attend this subject.

The Bioethics and History of Medicine modules are only taught with theoretical lectures and graded with a written examination. Each module weights 2 out of 20 for the final subject grade.

The other two modules, Biostatistics and Medical Informatics are taught with theoretical lectures, an e-learning component and practical lectures. Each one of these modules weights 5 out of 20 in the final classification (2 for the written examination and 3 for the work students do during the year at the practical lectures).

The 6 values necessary to complete the maximum grade of 20 come from a group project that is compulsory for all the students to complete at the end of the academic year. The group projects are supervised by the lecturers that help the students to understand and organize their work. In addition, students can attend seminars that give important information for the development and implementation of the group project.

Figure 1 - Moodle e-learning platform that is used within the Introduction to Medicine subject

B-Learning - integrating e-Learning components within the teaching process

The Biostatistics and Medical Informatics modules are taught with theoretical lessons (where the main concepts are presented to the students) and practical lessons (where the lectures support the students in their continuous self-learning process).

It is within the practical lessons that the integration of the theoretical concepts with the e-learning component available at the Moodle platform is made (Figure 1).

The practical lessons have the duration of 2 hours and a half every week and the students have access to their own personal computer. The lecturers start by discussing with the students the concepts given at the theoretical lessons and then these concepts are practised within the e-learning platform. The lecturers assess students' acquired knowledge (all the 239) individually with online mini-tests (Figure 2) at the end of every lesson. The mini-tests have a maximum duration of 5 minutes and include 2 or 3 multiple or numeric questions. These questions are selected randomly from a pool of questions that is created by the lecturers. The pool about a specific issue is big enough so that when students start the test they have most probably different questions to answer in their test or at least setup in a different order from all the other tests, so that copies among the students is almost impossible. All the information that is available within the Moodle can be accessed at anytime from any computer that has Internet connection. However, the mini-test can only be accessed during the practical lessons, only in some selected PCs where the lecturers need to insert a key so that the students can enter the right interface. This feature avoids problems with counterfeit of mini-tests because their results are taken into account for the students' final grade. When the 5 minutes expire the mini-test is corrected automatically and the final grade is showed to the student. If the student does not submit his answers before the mini-test finishes, the answers given until that moment are automatically submitted and the grade given accordingly.

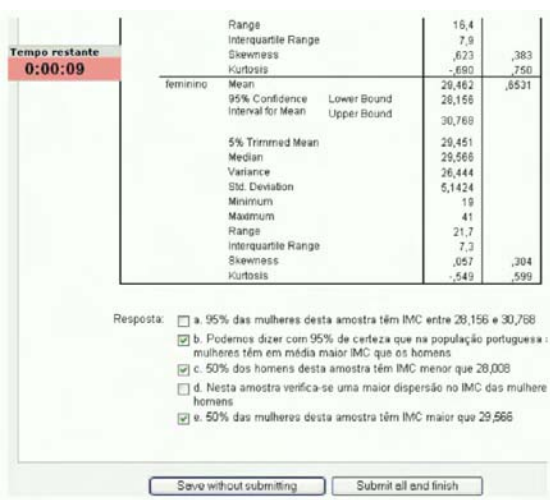

Figure 2 - Example of a weekly mini-test presented to the students, with automatic correction and timing

The average of all the results from the mini-tests can contribute to a maximum of 6 out of 20, which is the final grade.

Within the Moodle e-learning platform the content is organized on a weekly basis regarding each week of the academic year, in a total of 33 weeks.

Different types of content are included:

- SLIDES – the presentations made within the theoretical lessons;
- FORUM – used to exchange and share information about the subject between the students and the lecturers;
- EXERCISES – exercises to apply the theoretical concepts are made within the practical lessons and they allow the students to use real data from clinical studies. The tables with the real data that does not affect ethical issues related with the patients are also available in the Moodle.
- SELF-ASSESSMENT – the students can practice what they have learnt with self-assessment exercises with automatic correction;
- MINI-TESTS – these are exercises that count for the students' final grade. They are timed and corrected automatically by the Moodle;
- GROUP PROJECTS – the group projects are submitted by the students and commented by the lecturers within the Moodle, during 3 review phases;
- LINKS TO OTHER ONLINE MATERIAL:
  - MEDSTATWEB [6] - http://medstatweb.med.up.pt/ - the biostatistics interactive manual (figure 3) was developed by the lecturers and explains the basic biostatistics theoretical concepts with the use of practical examples and simulations (figure 4)
  - MEDICAL INFORMATICS - http://im.med.up.pt/ - the medical informatics manual was developed by the lecturers and explains theoretical concepts of Medical Informatics (see figure 5).

Advantages and disadvantages

Without an e-learning platform like Moodle it would be very difficult to make all the exercises and corrections that are done now because the number of students is too large compared with the number of lecturers.

This model allows students and lecturers to search and update the contents anytime, anywhere via Internet. It also permits the lecturers to monitor each student individually and the preliminary as well as final results of the subject and all the students in a generic way by allowing the analysis of the accesses that were made to its contents.

A disadvantage to consider can relate to the privilege that students with access to the internet at home may have in relation to the ones that do not have. To minimize this issue the students are encourage to use the computer laboratories within the Centre for Informatics at the FMUP that provide the Internet connection.

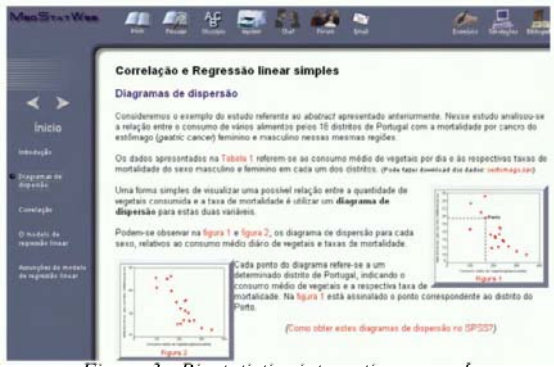

Figure 3 - Biostatistics interactive manual

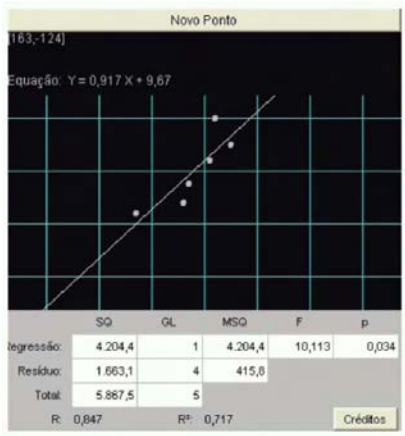

Figure 4 - Example of a simulation within the Biostatistics manual that explains the concept of regression. The user can move or insert points. The regression line is the ANOVA table and the relation coefficient automatically updated according to the points

Figure 5 - Medical informatics manual

Structure and implementation

The implementation and integration of the Moodle e-learning tool was done in collaboration with the Centre for Informatics at the FMUP. The contents have been developed, improved and updated by the lecturers during the past 10 years. In the academic year of 2005/2006 a group including 7 lecturers, the professor responsible for the sub-

ject and 2 other people from the Centre for Informatics at the FMUP integrated the contents of the subject within the Moodle platform, version 1.5.3 [7] along with a web server and a Mysql database server version 4. Both servers are shared with other services that the FMUP provides so the e-learning system does not have a specific server adjacent to it. Nevertheless, the performance of the system is not compromised. Both tools (Moodle and Mysql) are open source software so they do not bring additional costs to the FMUP. Furthermore, Moodle is a flexible tool, and being open-source software, it can be altered in order to adapt some of its functionalities in order to generate data and lists of relevant statistics to be used in this case study. The actual version of the Moodle does not include these functionalities.

The Moodle platform is available at http://moodle.med.up.pt.

The authentication platform to Moodle is synchronized with the authentication for the users of the FMUP allowing for its easier integration.

This platform was also used by integrate another subject form the Medical degree and 5 more subjects from a post-graduate summer course organized and lectured by the Biostatistics and Medical Informatics Department.

Results

Results for the use of the biostatistics module

The biostatistics module was lectured with theoretical and practical lessons during the first semester of the academic year of 2005/2006. During the course of this semester 227 students accessed the e-learning material available from Moodle. The students made an average of 1,4 accesses to each chapter of the interactive manual, the MedStatWeb, 1,5 accesses to each exercise of the practical component, 2,8 downloads of each set of slides from the seminars and 2,5 downloads of each set of slides from the theoretical lessons.

From the 227 students, 31 got an average grade inferior to 10 (out of 20) in the mini-tests, 149 got an average grade between 10 and 15 whilst 47 students got grades equal or superior to 16.

202 students wrote the final exam and the average grades of the Biostatistics module was 11.

We noticed that the students with better grades in the mini-tests were the ones that made more accesses to the MedStatWeb interactive manual and practical exercises within the Moodle. Although some of the students with better grades also made more downloads of the theoretical lessons' slides and seminars, these differences were not statistically significant (table 1).

Evaluation of papers

All papers will be reviewed by three (3) independent reviewers. Reviewers will use a standardized form for review, a sample of which appears on this Web site (click here for direct link to that form). Authors should be familiar with the criteria used in evaluation.

The students that got an average grade inferior to 10 in the mini-tests for this module got an average of 7 (standard deviation of 4) in the final exam for this same module. Those who got an average grade between 10 and 15 in the mini-tests got an average of 10 (standard deviation of 4) in the final exam. The students that got an average grade equal or superior to 15 in the mini-tests got an average of 14 (standard deviation of 4) in the final exam. These differences have a statistic significance (p<0,001 - One-Way ANOVA).

Table 1 - Median (minimum-maximum) of accesses made by the students for each type of content available in Moodle

	Average grades for the weekly mini-tests			
	<10 n=31	**10–15** n=149	**>15** n=47	**p***
Number of accesses during the first semester to:				
7 chapters from the interactive manual	8 (0-36)	10 (0-38)	13 (0-51)	**0,047**
10 exercises with real data	15 (6-25)	15 (4-29)	16 (5-33)	**0,033**
10 sets of slides – seminars	24 (1-136)	25 (0-125)	30 (2-66)	0,283
10 sets of slides – theoretical lessons	23 (2-91)	24 (0-73)	27 (5-56)	0,386

* kruskal Wallis test

Results for the use of the medical informatics module

The medical informatics module was lectured with theoretical and practical lessons during the second semester of the academic year of 2005/2006. During this semester 221 students accessed the e-learning material available in Moodle. The students made an average of 2,2 accesses to each exercise of the practical components, 2,5 downloads to each set of the theoretical lessons. From the 221 students, 37 got an average grade inferior to 10 (out of 20) on the mini-tests, 124 got an average grade between 10 and 15 and 60 students got an average grade equal or superior to 16. 202 students did the final exam for this module and the average grade was 12. The students with better average grades in the mini-tests made significantly more accesses to the practical exercises than the ones who did not. Although some of the students with better grades also made more downloads of the theoretical lessons' slides and seminars, these differences were not statistically significant (table 2).

The students with an average grade inferior to 10 in the mini-tests within this module got an average grade of 10 (standard deviation of 6) in the final exam on the same module.

Those who got an average grade between 10 and 15 in the mini-tests got an average of 13 (standard deviation of 5) in the final exam. The students that got an average grade equal or superior to 15 in the mini-tests got an average of 15 (standard deviation de 3) in the final exam. These differences have a statistical significance (p<0,001 - kruskal Wallis test).

Statistical data for the use of the platform

During the whole academic year the students made, within the Moodle, about 22 000 accesses to the slides used for

Table 2 - Median (minimum-maximum) of accesses made by the students for each type of content available in Moodle.

	Average grades for the weekly mini-tests			
	<10 n=37	**10–15** n=124	**>15** n=60	**p***
Number of accesses during the second semester to:				
6 exercises with real data	11 (2-23)	13 (0-38)	14 (6-45)	**0,026**
9 sets of slides – theoretical lessons	17 (0-39)	22 (0-77)	25 (1-60)	0,070

* kruskal Wallis test

theoretical lessons and seminars, 6 650 accesses to the practical exercises that relate with the theoretical concepts, 3685 downloads to real data databases, 10 383 submissions of the self-assessment exercises with automatic correction, 3 947 mini-tests that were included in the student final grade, 420 group project submissions and 94, 29 and 14 discussions made within respectively the forum shared between students and lecturers, the forum used only by the lecturers and the forum where news were announced to the students.

The e-learning model developed by the lecturers supports and motivates the study using other web material such as interactive manuals namely MedStatWeb and Medical Informatics manual.

There was an average of 53 daily visits was made to the MedStatWeb, with 2565 hits per day. Each student made an average of 6 visits per month on this same manual. There was an average of 38 daily visits to the Medical Informatics interactive manual with a total of 587 per day. Each student made an average of 5 visits per month on this same manual.

Anonymous survey applied to the students

At the end of the academic year of 2005/2006 anonymous surveys were completed by the students that attended the subject of Introduction to Medicine and came to write the final exam (n=170). 90% of the students agreed that there was a good relationship between students and lecturers, 82% that the subject was well organized, 79% that it was easy to access the available material, 75% believe that was motivated by the interaction of the practical lessons, 65% thought that was able to pay attention and be interested during the lectures, 59% said that they accessed the online material on a regular basis, 54% stated that they could study regularly the subject and 36% said they attended the theoretical lessons regularly.

Final results

From the 239 students registered to attend the Introduction to Medicine subject, 231 were assessed from which 204 (88%) were successful and 12% failed. The average grade among the successful students was 16 (out of 20). In the previous academic year, when another e-learning platform was in use only 2% of the students failed. However, among the successful students, the average grade was inferior (15 out of 20).

Conclusions

The e-learning model that was described in this paper was successful because the results show that the students that made use of the Moodle got better grades. Also, the results from the survey illustrate that a vast majority of students think that the subject I well organized and that was easy to access the available study material. They also agree they were motivated to participate more actively in the learning process.

It is important to refer that the significant statistic differences reflect the fact that students that access more the online exercises and simulations are the ones that got better grades, not the ones that made most downloads of the lectures content material.

However, it is surprising that the students made so many downloads from the slides available since one download and printout for each set of slides would be enough.

According to the results obtained the mini-tests are beneficial for the students learning process. The students that could not obtain a satisfactory grade in the mini-tests could not obtain a similar grade in the final exam. On the other hand, the students that got good grades in the mini-tests were able to get the best results in the final exam.

This e-learning platform facilitates and simplifies the lecturers work because it would be very hard for them to correct 200 mini-tests every week and give the students the updated feedback every time. The integration between the traditional teaching with the e-learning was successful as 90% of the students agree that there was a good support between them and the lecturers and this happened mostly during the practical lessons.

In conclusion, although the percentage of failed students was bigger than in previous years (reflection of a tougher final exam because lecturers thought the students were better prepared this time), the final grades obtained for the Introduction to Medicine subject were very satisfactory because the students that passed the final exam had generally better grades than the ones in previous years.

For the future use of the Moodle platform the layout needs to be improved to be better adapted to the FMUP characteristics and objectives. Also, the use of forums and discussion groups will be more encouraged as they can help the students to clear their doubts and discuss the lecturers' topics in a more informal way.

Acknowledgements

We would like to thank the Introduction to Medicine lecturers for the academic year 2005/2006 that are not co-authors for this paper but participated actively in this e-learning project, namely Luís Filipe Azevedo, Filipa Almeida, João Fonseca and Mário Ribeiro. Further we would like to thank other collaborators such as: Camila Dias, Clara Tavares and Pedro Marques, as well as Armando Teixeira Pinto and Alberto Freitas that did not lecture this specific academic year but have contributed in previous years to improve the use of the e-learning tools. Finally, special thanks to Miguel Ângelo from the Centre for Informatics at the FMUP that contributed with the implementation of the Moodle layout.

Designing m-Learning for Junior Registrars – Activation of a Theoretical Model of Clinical Knowledge

Anne Marie Kanstrup[a], Niels Boye[b], Christian Nøhr[a]

[a] *Virtual Centre of Health Informatics, Dept. of Development and Planning, Aalborg University, Denmark*
[b] *Regional Hospital of Randers / Aarhus University Hospital, Denmark*

Abstract

The MINI-project aims at supporting junior registrars in the learning process of how to utilize their theoretical knowledge from Medical School in everyday clinical reasoning and practice. Due to the nature of the work – concurrent moving, learning and producing - we designed an m-learning application. This paper introduces the possibilities and challenges for design of the m-learning application based on a) analytical findings on learning and mobility as derived from the design case – an emergency medical ward b) theoretical perspectives on medical knowledge, and c) presentation of the design of an m-learning application. The design process was based on user-driven innovation and the paper discusses considerations on how to combine user-drive and generic models.

Keywords:

software design; user-computer interface; medical informatics applications; decisions support systems, clinical knowledge; physician practice patterns; clinical reasoning; diagnostic reasoning; handheld computers; guidelines; education; internship

Introduction

Handheld computers or personal digital assistants (PDAs) have become common in clinical settings, and are used by physicians as well as nurses [2; 6]. The most common functions for PDAs in clinical settings are to provide clinical reference guides for drug information, patient tracking and various clinical guidelines. Increasing wireless connectivity combined with more patient data in digital form, introduces new application areas such as electronic prescribing, real-time medical records access and point-of-care evidence-based literature searches [13]. This paper reports from the MINI-project which is experimenting with the use of handheld computers for mobile e-learning/ m-learning to support physicians' introduction to clinical work. The case is an emergency medical ward at a large regional hospital in Denmark.

The case: learning and mobility at a medical ward

During their first years of medical practice physicians need to operationalize their knowledge from medical school, in the terms of Dreyfus & Dreyfus going from "knowing that" to "knowing how" in stages from novice to competent [5]. The current practice for supporting physicians in this learning process is an apprenticeship process [10] where junior registrars make experiences in daily hospital production and 'reflections on action' with chief physicians. The 'reflection *on* action' [14] is organized formally in conversations taking place during shifts, x-ray and other conferences but can alternatively, if the problem justifies it, take place "on the fly". At these conferences physicians (junior registrars and chief physicians) discuss their experiences, diagnoses, the situation and status of patients at the ward, care plans, etc. When it comes to 'reflection *in* action' [14], the back-up of registrars and conversations between novice and experienced physicians is, however, more difficult especially due to time pressure and lack of resources. Photograph 1 displays the ward used as case and is taken during ward-rounds displaying a typical situation of contact between junior registrars (standing in a circle) and an experienced chief physician, here briefly passing by answering questions and giving suggestions and then on to the next patient. At a design-workshop focusing on learning resources when on duty, junior registrars expressed how "you are mostly alone when on duty and when making your decisions" and how "one of the difficult things to learn is to make decisions on your own". Their back-up for decision-making is carried in the pockets of the white-coat, which is stuffed with reference books, instructions and guidelines, personal notebooks, etc. as seen in photograph 2.

Photograph 1 - Chief physician giving brief advice to registrars on duty. Photograph 2 - The pockets/back-up of a registrar (2,6 kg).

The objective of the MINI-project is to experiment with design of m-learning [11] to support physicians especially in their first period of clinical work as junior registrars. The aim is to design ePockets to replace the paper pockets displayed in photograph 2 and more importantly to improve knowledge support for decision making by inexperienced but professional physicians: the right information, at the right time, at the right place, and right at hand via mobile technologies and m-applications.

Empirical work at the ward/with staff (observations, interviews, conversations, workshops, design-meetings) has pointed out the following important characteristics for learning and mobility in this specific design context [7]:

- Mobile means walking – the physicians walk while looking up information and interaction techniques for 'one the move-interaction' like one hand interaction, is important.
- Mobile means on the way to the next task – maximum time for looking up information or making notes is 3 minutes and navigation supporting 'easy to find' is important.
- Learning at work is filled with interruptions – the physicians are constantly interrupted and as a consequence working hard to keep track via personal notebooks on their patient. It is important not to design yet another interrupting artifact but rather a personal device supporting their tracking of their work.
- Learning takes place in situ when working. Consequently it is important that the learning content is related to this 'situ' (vs. general information from reference guides, etc.)
- These characteristics of mobility and learning challenge the dominant 'office-domain' and call for experimentation with interaction techniques and content development (e.g. from text towards AV or VR).

Methods: user-driven innovation and (generic) models

The primary outset for the design process has been user-driven innovation in order to root the design in its context [8]. The sustainability of the specific design is to be seen in this perspective – an information ecological perspective to design and use of information technologies as an interwoven part of practice, values, people and technologies [12]. User-driven innovation is a meeting-point for designers and users making it possible to swap roles and bring use-practice, values and users to the foreground of design-processes. Hence, user-driven innovation provides a nice point of departure for sustainable software development from an information ecological point of view.

To combine design and use, theory and practice, is, however, not an easy task solved by involving users in the design process. A significant but very difficult aspect of software development in a wider perspective than just one case (one information ecology) is the development of generic models which make it possible and easy to make, share, maintain, and not least understand applications. Experiences with development of Electronic Health Records (EHR) emphasize this difficulty where the concept of archetypes has been elaborated for many years and where the goal has been sustainable systems with an easy exchangeable knowledge component [3]. Currently, a similar picture is surfacing within the area of providing online instructions or guidelines to medical staff in Denmark. Several different projects are emerging most of them focus on transmitting information to the WWW or PDAs. In the MINI-project we have developed a theoretical model for clinical knowledge as the important basis for understanding the problem to be supported and not least as a basic model for the designed m-learning application. The following presents this model and how it has been activated in the design of our MINI-m-learning application.

Towards a model of medical knowledge

Our employed model of knowledge in the medical domain is inspired from Adolfsen's epistemological model of everyday problem solving, where knowledge is stratified in three layers [1]. We define medical knowledge as consisting of three interrelated layers.

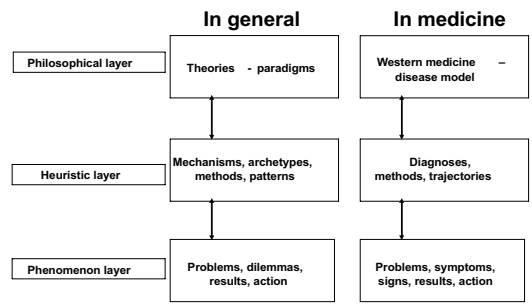

Figure 1 - The employed model of knowledge. The western medicine model is simple and says: "That to every disease or syndrome is a specific lesion, this can be functional, anatomical, physiological, biochemical, genetic, or social". Another model in the philosophical layer is Watson & Cricks model of DNA. For the other parts of the figure, see text for explanation.

The figure shows how the same dilemma can co-exist in three appearances of abstraction: in the bottom level the concrete everyday problem in contact with the everyday action and environment. In the middle heuristic layer, as a general problem, an archetype, a pattern, a diagnosis, or a method. In the upper model layer, as a theory or philosophy.

A medical example:

- bottom level – the patient's problem: palpitations corresponding to the doctors problem in this phenomenon layer: tachycardia (fast heart-rate)
- In the heuristic, archetypical layer the disease entities that can cause fast hearth-rate are located: e.g. thyrotoxicosis, fever or heart disease (there are many more).

- At the theoretical level are factors promoting a fast depolarization of the sinus node in the heart.

There are multiple other causes of fast hearth-rate than given in this example, this serves as an illustration of the different instantiations of the same problem and that "clinical reasoning" is translation and knowledge acquisition, activation, and operationalization (only possible in the phenomenon-level) in the different layers and this is not a strait forward algorithmic exercise. A recent review article "Educational strategies to promote clinical diagnostic reasoning" discusses this in detail mainly in the phenomenon layer [4].

Doctors need to master a problem in all three layers including the action relevant to diagnostic and therapeutic procedures. Patients have their primary interest and attention in the phenomenon layer, since the concrete problems are experienced in or on her body. Patient education efforts aim at bringing patient knowledge and reasoning to the heuristic layer, and thus provide them with "higher level tools and understanding" in cope and self-care of their disease problems.

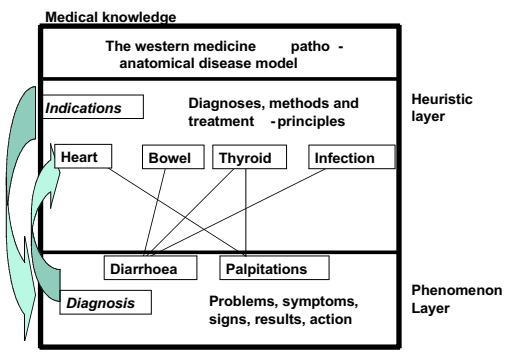

Figure 2: Example of the (non-algorithmic) dynamics of operationalization of medical knowledge. A patient presents diarrhoea and palpitations as problems. The doctor generalizes these problems to diagnoses in the diagnostic process. During this he activates knowledge from the upper theoretical layer. After the diagnostic process an indication of treatment is formulated employing both theoretical and heuristic knowledge about treatment principles. The principle is brought into action tailored to the specific problems and patient. The explanation for the choices made is "the indication" for the treatment.

Designing m-learning for medical knowledge

This perspective on medical knowledge put emphasis on support for the bridging between the different layers of medical knowledge – the relations – when designing m-learning for physicians in medical training i.e. focus on the heuristic layer as the meeting point for relations and support knowledge to and from this point. This perspective and focus is not new in the practice from the medical ward used as case. The heuristic layer is currently supported by the ward-instruction "the acute" organized in archetypes (heuristics for the ward e.g. 'the patient with fever, 'the arthritic patient', etc.) with relations to both the phenomenological layer (e.g. symptoms) and less prominent the philosophical layer (from University studies).

Consequently, based on both empirical analysis and the theoretical perspective on medical knowledge, the point of departure for the MINI-project has been to digitalize archetypes a) because it is learning content related to the specific use situation of the m-learning application b) because it supports the relations in medical knowledge grounded in the heuristic layer. It implies that the junior registrars are respected as professionals able to perform "clinical reasoning" and activate different layers of relevant knowledge regarding the specific patient – to fit a patient into a correct archetype and perform the necessary individual patient specific adjustments from this non-existing, average patient described in the archetype.

The transformation of existing paper archetypes into digital archetypes was carried out on the basis of a modified general work-flow model: with four "milestones" – all situated in the phenomenon layer: conclusion of the diagnostic interview (anamnesis, symptoms and signs) – often the basis for activating a specific archetype

1. Checklist of symptoms and signs contained specific ideas for further and alternative information relevant to a more precise positioning of the patient within the range of the archetype diagnoses.
2. Checklist of diagnostics, objective findings and test – contained relevant ideas for specific hospital procedures.
3. Checklist – treatment-plans
4. Checklist – monitoring and alternative actions.

In the technical dimension transformation of the paper archetype aimed at:

- A structure useful for a database
- Software useful as editor for producing archetypes within this structure
- A navigation design for MINI-archetypes/PDA-interaction

Microsoft Word™ was used as editor for production of the text for digital archetypes. Microsoft Word™ was used for producing the existing text for ward instructions and therefore well-known software to the archetype-producers (staff specialists). The archetype-producers were allowed to mark and prioritize the order in which they entered the text for later hyperlinking by means of a parser constructed by the programmer in the MINI-project.

The mini-mizing of the rather long text for each archetype (some were up to 25 regular pages in Microsoft Word™) was done by carefully designing the navigation for application. In order to work with the call for 'easy-to-find-information-while-walking-in-3-minutes' we have

- focused on the understanding of not only the screen of the PDA but also *the hardware as interface*. A short-

cut to the MINI-application was programmed and works by activation of a button at the front of the PDA.

- focused on gathering central information in *a MINI-frontpage* giving easy access to 1) instructions organized in archetypes with search function in the four areas presented in figure 3, 2) personal notes, 3) tables and 4) link to the Danish website for medical handbooks, drug catalogues etc. used very often – and carried in heavy books – by physicians. A click on the logo of Aalborg University always present in the top of the screen brings the user back to the MINI-frontpage (fig. 3a)
- focused on providing direct access to specific information via *search functions* facilitating free text search or providing access to information by means of lists of symptoms, diagnostics, treatments, and monitoring (fig. 3b)
- focused on providing overview of the rather long text for archetypes by giving a) an overview of headlines (designed in the editor and in co-operation with the archetype-writers/chief physicians) under which text can be unfolded by clicking the drop-down icon, b) giving 'at a glance' information on whether there are notes to the text by using a transparent icon of a document when no notes are available and making this icon clear when notes has been inserted. The same icon with the '+' is the icon used when inserting notes to the text (fig. 3c).

Fig. 3 - Screen-dumps from the MINI-application showing a) the frontpage of the application, b) search functions and c) a mini-mized digital archetype organized in headlines which are unfolded/folded by use of the drop-down icon and linked to notes by use of the note/paper icon.

A real challenge related to mobile interaction has not only been organizing of long texts but also mini-mization of rather large tables often used by physicians. Figure 4a shows an example of an often used table in 'real size' which, if minimized 1:1 would be impossible to read. An area in the table makes no sense if not related to other areas or at least to the columns and rows. Consequently we programmed the interaction in the table with fixed columns and rows and scroll within the areas (fig. 4b).

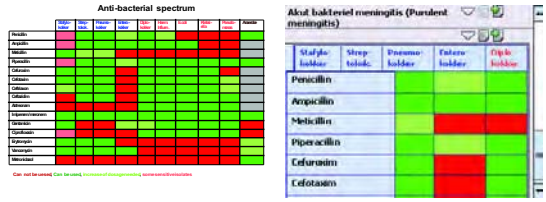

Figure 4 - a) a table in 'natural size', b) a screen-dump of the table in the MINI-application displaying the need for navigation here handled by keeping fixed columns and rows while scrolling in the table.

Ambitions of experimenting with voice interaction, primarily when making notes, failed due to technical problems but are on the top of a list for further research and development of the prototype.

Discussion: sustainability between user-drive and generic models

In the user-driven design process physicians were primary drivers behind the presentation and modeling of the clinical knowledge (their knowledge!) which was used in the design of the MINI-prototype by interaction designers. It is our impression that sustainable design cannot be identified at its source, in a (one!) practice (one information ecology) only. Likewise sustainable design cannot be validated on the generic potential of a model. Sustainability rather seems to lie in the interrelationship between the two – an interrelationship between user-drive and generic models which should not come as a surprise to software designers. However, it should emphasize (what cannot be emphasized enough) the importance of close collaboration between software developers and clinical personal in design processes. Further challenges and perspectives of the MINI-project are both the evaluation of the prototype but also inquiries into the use of PDAs at a national level. Both evaluations are taking place in the winter and spring of 2007.

Conclusions

The paper has presented results from the MINI-project on design of m-learning for physicians in hospital training. We have presented a) contextual findings on mobility and learning in the context of a medical ward, b) theoretical perspectives on medical knowledge, and c) description of our activation of this knowledge in the design of digital archetypes for PDAs.

It is argued that the user-driven innovation process of the project has provided a useful and valuable platform for sustainable development: it has both provided a platform for user-drive in the specific use-practice and provided the development of (steps towards) a generic model of clinical knowledge useful for further development and design projects. In other words, the user-driven innovation process has forced us to emphasise the combination of design and use and theory and practice – a combination which we have argued is essential to sustainable design.

Acknowledgments

We acknowledge the work of Pernille Bertelsen, Ellen Christiansen, and Thomas Christiansen and thank physicians at the ward for participating in observations, workshops, discussions, and pilot-test. The MINI-project is granted by the Danish Ministry of Science and Technology.

Evaluation and Assessment of the Online Postgraduate Critical Care Nursing Course

Reena Patel

School of Nursing, University of Auckland, New Zealand

Abstract

During challenging times facing the health service, strategies for sustaining further education for nurses in highly specialised areas call for alternate means for learning. Nurses, who were accustomed to traditional methods of learning and had no formal computer training as part of their curriculum, are now being confronted with new methods of learning. Evaluation of the effectiveness of a newly developed postgraduate critical care course delivered online for nurses was examined. A pre test and post test of 16 participants were conducted. Participants found coursework intellectually stimulating and their preference to learn from websites demonstrated the effect size (tau-b = .677) to be significant at the 0.01 level. The pre and post test results from the knowledge assessment tool indicated an advancement of mean test scores and at a significant difference value of p = .055. Ninety four percent of the participants agreed that they were able to integrate their learning from the coursework towards their clinical practice. Improvement in nurses critical care knowledge impacts positively on delivery of safe and effective health care.

Keywords:

education, nursing, critical care, computer assisted instruction

Introduction

Development of knowledge in the field of health is synonymous with using computer technology. The existence of the Internet and the vast amount of information available at the fingertips is the reality for nurses today. Computer technology is used to provide further education to nurses employed in critical care environments.

Traditional classroom settings are being replaced by the use of web-based and resource supplemented packages for continued learning [1]. To meet the needs for access and convenience, postgraduate nursing courses are being offered via distance learning environment [2]. As new web-based nursing courses emerge, the emphasis to examine quality means that evaluation and assessment need to be considered.

The increasing reliance on technology has become more apparent within the health science disciplines and has been integrated into many courses. The use of technology in nursing education has been directly extended into both graduate and postgraduate programmes. Nurses, who were accustomed to traditional methods of learning and had no formal computer training as part of their curriculum, are now being confronted with new methods of learning.

These new methods of learning for students encouraged more autonomy in learning [3]. Previously, the use of chalk and blackboards were the primary modes of communication in classes. Later, the use of overhead projectors, whiteboards and markers came to use. Eventually computers were integrated into the teaching and learning process. Today, the convenience of a learner having access to a course material anytime and anywhere [4] has removed the barriers of time and distance previously imposed by traditional classes [5]. The increased emphasis on technology in health care and nursing education should facilitate the development of flexible, knowledgeable and technologically competent practitioners [4].

This paper discusses the effectiveness of a newly developed critical care course delivered online as part of a postgraduate certificate program for nurses. Research is required to evaluate the effectiveness of online instruction, in the development of new knowledge and skills [6]. Additionally, the study examined the critical care nursing course for enhancing knowledge attainment and for student satisfaction with web based learning.

Methods

The longitudinal study design involved one study group of sixteen students. All participants completed the Online Post Graduate Specialty Practice Adult/Paediatric Critical Care nursing course. The design involved data collection at two intervals, prior course commencement, and at course completion. The questionnaire examined student application to course material and evaluation on the effectiveness of the online course. Critical care nursing knowledge was assessed utilising a tool known as the Australian Basic Intensive Care Knowledge Test (ABICKT) [7]. ABICKT was used to test participants prior to commencing the online critical care course. On completion of coursework at the end of semester two the test was reapplied to determine any difference in scores.

Results

Learning with technology

Results were obtained from a series of questions related to learning with technology. It was important to ask questions to the participants pertaining to whether additional learning and training with technology was required prior to or during the course. The participants responded to questions related to the ease in navigating around the course and their satisfaction towards the technical access to the course.

Prior to commencement of coursework, an introductory seminar regarding the means of accessing coursework and assessments was demonstrated. Participants were asked in the post course questionnaire if they had found that they required additional technological learning when course content was commenced. Of the 16 participants, 10 (62.5%) of them agreed that additional learning was required. Only 4 (25%) participants strongly disagreed that no additional technological learning was required when commencing the course content.

The post course questionnaire sought data on responses from participants regarding the ease of navigation around critical care course materials. Course materials consisted of Internet web site addresses, Microsoft PowerPoint presentations, online journal articles from the university course library page and coursework set out in Microsoft Word documents.

Results from this question indicated that 11 (68.8%) of the 16 participants found it easy to navigate around course materials and 5 (31.3%) found it somewhat difficult. Participants were then asked if they were satisfied with the technical access to the coursework. Of the 16 participants, 13 (81.3%) were satisfied with the technical access compared to 3 (18.8%) participants who disagreed to this statement.

Correlations between data obtained from participant's experiences with technology and levels of support were considered. The most significant correlation seen at the 0.01 level was between the data related to participant's satisfaction with technical access to coursework and their ease of navigation around the coursework material. The correlation was investigated using Kendall's tau_b correlation. Expectedly, there was a positive association between these two variables, p= 0.01 and tau_b = 0.55 (see Table 1).

Table 1 - Correlation of the variables for online learning experiences

		Ease to navigate in course	**Satisfaction of technical access for coursework**
Adequately prepared for technology used in course	Correlation Coefficient	.532(*)	.512(*)
	Sig. (1-tailed)	.012	.014
	n	16	16
Ease to navigate in course	Correlation Coefficient	-	.549(**)
	Sig. (1-tailed)	-	.009
	n	-	16

* Correlation is significant at the 0.05 level (1-tailed).
** Correlation is significant at the 0.01 level (1-tailed).

Interestingly, when the strength of the relationship between ease of navigation in the course and the participant being adequately prepared for the technology used in the course were considered, there was a strong correlation at the 0.05 level, p= 0.12 and tau_b = 0.53 (see Table 1).

Correlation between a participant's satisfaction with technical access to the coursework and being adequately prepared for the technology used was also considered. Again the results from Kendall's tau_b analysis showed a significant positive association between these two variables p= 0.01 and tau_b = 0.51, at the 0.01 level (see Table 1).

Coursework satisfaction

On completion of coursework and assignments, the post course questionnaire sought the responses from participants in relation to their advancement in critical care nursing knowledge. Of the 16 participants, 4 (25%) strongly agreed with this statement and 12 (75%) somewhat agreed (see Figure 1). There were no participants who disagreed with this statement. Further, they were asked if they were able to integrate course learning with their clinical practice. Of the 16 participants, 15 (94%) responded by strongly agreeing and somewhat agreeing to the statement (see Figure 1).

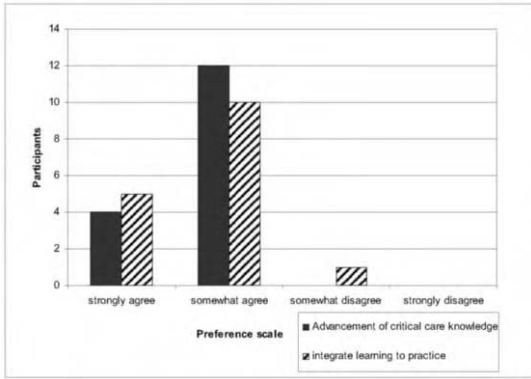

Figure 1 - Integration of advanced critical care knowledge to practice

The critical care course provided current world wide web (www) addresses as adjuncts to course learning. In the post course questionnaire participants were asked as to their preference for learning from these websites. Of the 16 participants, 11 (64.7%) preferred learning from websites and 5 (31.2%) indicated they did not prefer this method of learning (see Figure 2).

All participants were asked to indicate whether journal articles for each topic contributed to an increase in their understanding of the subject. Of 16 participants, 14 (87.6%) participants agreed that the journal readings deepened their understanding and 2 (12.5%) participants somewhat disagreed to this statement. There were no participants who strongly disagreed regarding the contribution of journal articles to the coursework learning and understanding (see Figure 2).

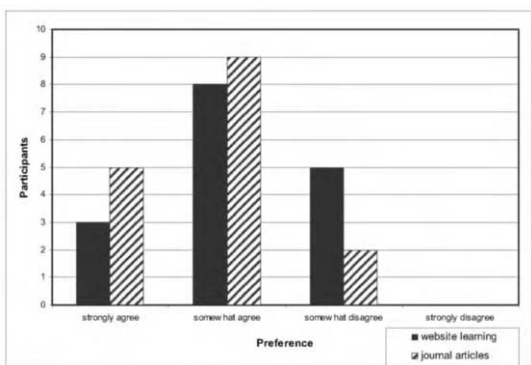

Figure 2 - Preferences of learning method

Importantly, there was a strong correlation between participants' use of online journal articles and their ability to integrate course learning to practice, p= 0.001 and tau_b = 0.726. Those participants who found coursework intellectually stimulating also reported a preference for learning from websites. This correlation was seen at a level of p= 0.002 and tau_b = 0.68, which was significant at the 0.01 level.

Critical care nursing knowledge test

Results from the pre course and post course critical care nursing knowledge test findings are presented. The post-test results revealed no changes in the number of higher scores (i.e. number of participants who achieved marks 80%). What it did reveal, however, was a positive shift of scores from the 60th percentile to the 70th percentile for several participants (see Figure 3).

The calculated median for the pre test results was 66, and the median for the post-test results was 71. This demonstrated an improvement of test scores post completion of coursework and assessments.

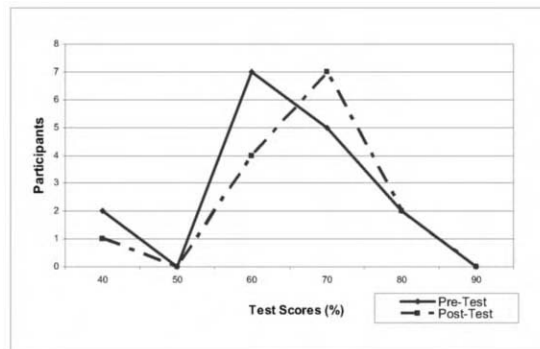

Figure 3 - Pre course and post course critical care knowledge test results

Wilcoxon Signed Rank test was used for analysis of the pre and post ABICKT results. It indicated that the two set of scores were approaching significant difference at p = 0.055. The median for the pre and post knowledge assessment test was 66 and 71, respectively. The median increased by 5% in the post-test. The majority of the participants achieved a score greater than 60% and below 90% in both the pre and post-test. There was a 10% increase in scores for some participants who scored 60% in the pre-test.

Discussion

The study examined the effectiveness of coursework learning and the application of the knowledge acquired to clinical practice. In nursing, the capacity to blend nursing education with clinical competency and problem solving skills has been a growing demand within the nursing profession. Dunn et al [8] and Morrison [9] have suggested that the ability to master the cognitive facts and apply the knowledge with critical problem solving and psychomotor skills in a clinical situation can be correlated with competency. The applicability of learning in the course to the clinical setting was relevant.

All participants in the course had indicated that they perceived their critical care learning had advanced. When questioned about how their learning was being applied to practice, 94% agreed that they were integrating their new knowledge to clinical settings. Nurses working in critical care particularly valued their training in physiology-based

decision-making. Saggs [10] highlighted this view and considered that physiology decision-making and practice skills were considered extremely relevant to postgraduate education in critical care. Equally significant, as discussed by Manias and Aitken [11], was the importance placed on nurses achieving technological competence in critical care.

In this investigation although there was a favourable outcome, one participant felt that their skills had not advanced in the clinical setting. In accordance to principles of Gestalt psychology, learning is perceived in different ways depending to the learner's experiences [12, 13]. The fact that this particular participant had not transferred new learning to clinical practice, suggests the level of exposure to clinical experiences need to be explored. Toth [14] concurred and proposed that increased knowledge occurs with more experience.

The relevance of content learned and its applicability to clinical practice was also examined in the study. Knowles et al [15] has pointed out that learning occurs not only when one is exposed to learning materials, but also occurs in the workplace. In the workplace, one is able to apply higher thinking processes leading to the interpretation and understanding of new learning. This has been well documented by learning theorists, who emphasised that adult learners need to know why they are learning something and then understand the meaning of it when applied to their real world [13, 16-18]. Content and intended learning should be related to the needs of the nurse in order for it to be applicable in practice.

Motivation to learn goes hand in hand with engaging the student with the learning material and ensuring the provisions of adequate intellectual stimulation. The results from this course evaluation showed that students perceived that the course had motivated them to learn, they had a clear idea of what was expected of them as they proceeded with coursework, which they were able to cope with. Online instruction engaged students in an interactive learning environment that extended beyond the classroom and increased their access to the wealth of educational resources online [6].

The online critical care course provided postgraduate study for nurses who were employed in critical care units. A variety of nurses were able to enrol into the course for example those who were new to practice, those seeking career development, or those who were re-entering into the critical care specialty. Students used technological competence to make sense of the critical care environment and to support and extend their existing practice. Wynd [19] proposed that critical care knowledge improved when nurses participated in specialised critical care courses which developed critical care experience. In this study, critical care nurses displayed an earnest desire to improve their knowledge and skills.

Interestingly, a strong association was seen between the variable of participant's use of journal articles for learning and the ability of participants to integrate course learning to clinical practice. A correlation of $p = .01$ and an effect size of tau_b - .726 was observed. Journal articles were all online and focussed on the topic objectives. Equally important was gaining information and learning from websites, yet only 65% of the participants preferred this mode of learning. This revealed differences in the manner students interacted with computer-mediated learning materials. Although learning involved printed material and computer mediated material, Benson [20] observed that learning via online instruction involved more than just obtaining lecture notes from technology mediated programs. It involved an integration of delivery options available for interactivity and learner engagement with the online content.

Interactivity has been considered to represent two-way pathway for the flow of information between the facilitator and the participant [1]. In this investigation, the high levels of interactivity have encouraged learners to participate in learning activities. As a consequence they have demonstrated enhanced retention, transfer of learning and satisfaction [20].

Conclusion

The use of technology in higher education has grown exponentially. In order to establish the worth and merit of these programs, careful evaluation needs to be conducted. Williams [21] has suggested that since there was no norm with which to compare how well learning with technology has worked, conclusions as to whether a program has in fact improved learning outcomes need to be examined critically.

The primary outcome of the research indicated that all participants perceived an increase of critical care nursing knowledge after completion of all coursework and assignments. Ninety four percent of the participants agreed that they were able to integrate their learning from the coursework towards their clinical practice.

The secondary outcome of the research indicated that the pre course and post course knowledge assessment test indicated an advancement of mean test scores and at a significant difference value of $p = .055$ in test scores.

As discussed by Williams [21], evaluation can prove to be a powerful partner for improving higher education, as long as relevant participants are involved in the process. It should be discussed in the context of its users and its purpose. To keep up with our changing society, nursing and nursing education should continue to develop innovative ways of teaching, reflecting the past but setting new directions for future knowledge and providing safe and effective health care.

Acknowledgements

This paper is based on research undertaken for Master of Health Science, Health Informatics, with thanks to Michelle Honey, fellow nurse and supervisor.

Abstract

Depression is under recognized in a variety of pediatric settings. The purpose of this paper is to describe the development and initial evaluation of a personal digital assistant (PDA)-based decision support system (DSS) for pediatric depression screening in ages 8 to 18 years of age by pediatric advanced practice nurse (APN) students. Three aspects are described: selection of depression screening instrument; integration of the instrument into the PDA; and quantitative (usage) and qualitative (focus group) evaluation. Only one third of eligible patients were screened. Twenty percent of those screened were identified as at risk for mood disorder. The barriers to screening identified through focus groups included a lack of time, knowledge, intervention protocol, referral resources, PDA usability issues, preceptor motivation and comfort, as well as perceived or real cultural barriers. Suggestions for educational, research, and interventions to integrate clinical based PDA-based screening are discussed.

Keywords:

depression, mood disorders, child, pediatrics, primary health care

Introduction

Childhood and adolescent depression is a serious public health problem [1]. Modern interest in child and adolescent depression arose in the late 1970 [2] and over the past 30 years, there has been an increased recognition of pediatric mood disorders [3]. It is estimated that depression occurs in 9 per 1000 preschoolers and 20 per 1000 school-age children [4]. The prevalence of a major depressive disorder (MDD) by late adolescence is ranges from 14 to 20% [5-8]. Depression is a risk factor for suicidal behavior [9], reduced social functioning [10], long term effects on neurocognitive functioning [11-12], poor school performance [13], serious conduct disorders [14], and drug use [15]. Untreated depressive disorders during childhood and adolescence can herald the onset of chronic and recurrent disorders during the person's lifetime [16-17]. Thus, early identification of children and adolescents at risk for a mood disorder is an important issue for clinicians.

While suicide can occur without previous depression in children and adolescents [18], depression is also sometimes a precursor to suicide During the last few decades, the suicide rate has steadily increased reaching a peak in the late 1990s [9]. Over the past few years the suicide rate has not changed substantially and at present, the rate of successful suicide is .6 per 100,000 in 5-14 year-olds and 9.7 per 100,000 in 15-19 year olds [19]. In addition, a history of prepubertal suicidal behavior predicts suicide attempts in adolescence [20-21]. Consequently, in screening for mood disorders, it is important to screen separately for suicidal ideation.

Health care providers in a variety of settings are in a unique position to identify, manage, and coordinate care for children with mental health disorders including depression [22]. Furthermore, the lack of child mental health specialists has placed an increased burden on primary providers to identify and treat children with behavioral health problems [23]. Multiple studies have confirmed that there is an under identification of mental health disorders in primary care settings [24-26]. If the provider does not use a standardized screening instrument, the detection of children with behavioral problems is lower [28-29].

At Columbia University School of Nursing, a PDA-DSS was designed to aid APN students to document and analyze patient encounters and to provide decision support for the screening and management of obesity, depression, and smoking cessation. A randomized controlled trial is in progress. The purpose of this paper is to describe the development and initial evaluation of the PDA-DSS for pediatric depression screening in ages 8 to 18 years of age by pediatric APN students. Three aspects are described: selection of depression screening instrument; integration of the instrument into the PDA; and quantitative (usage) and qualitative (focus group) evaluation.

Materials and methods

Selection of depression screening instrument

A Medline search was conducted combining the key words of mood disorders, pediatric depression screening, primary health care, and pediatric depression. In addition, an Internet search for pediatric depression screening was

conducted. The search yielded twenty different instruments with acceptable specificity and sensitivity statistics. Team members with expertise in pediatrics, psychiatry, and psychometrics evaluated the tools taking into account age range, length of questionnaire, and population that the instrument had been tested in.

Integration of the instrument into the PDA application

Questions from the screening instrument were added to the knowledge base that supports the PDA application. The content and algorithm were implemented for the Palm OS using the AppForge development environment.

Usage

SQL queries were developed to retrieve the data associated with depression screening from the central database. The following data were retrieved from the database for the time period of September 1, 2006 to November 26, 2006: the number of depression screening encounters versus the number of eligible depression screening encounters; medical diagnoses of those identified as at risk for a mood disorder and those not at risk for a mood disorder; characteristics of encounters in which pediatric depression screening occurred (patient demographics, family history of depression).

Focus groups

The objective of the two focus groups was to gain an understanding of the knowledge, attitudes, and beliefs of APN students regarding the use of a PDA-DSS. A purposive sample of 6 first and 6 fourth semester pediatric APN students were invited to participate in a 1-hour focus group. A 10-question, investigator-developed, interview guide was used to facilitate the discussion. The questions were developed from discussions with a panel of doctorally-prepared experts in informatics and qualitative research methods, as well as from a review of the qualitative literature on the attitudes of physicians [33-34] regarding PDA use in the clinical setting.

At the beginning of the group, each participant was given a copy of the interview guide. An experienced psychiatric clinical nurse specialist (PB) and an experienced pediatric APN (JCH) each conducted and facilitated one of the focus groups. An observer (RJ) took notes and audiotaped the discussion. During group discussion, the facilitator put forth a question and participants responded while interacting with one another. Probes were used to gain more detailed information and personal accounts. Data were content analyzed to extract major themes related to knowledge, attitudes, and beliefs.

Results

Depression screening instrument

After a careful review of the literature [30-32] and discussion among research team members, the team selected the Short Mood and Feeling Questionnaire (SMFQ) to measure risk for mood disorders rather than a longer diagnostic instrument. An addition four questions were added: two related to family history of depression [3] and two related to suicide [18].

Integration of the instrument into the PDA application

The SMFQ was displayed using 3-4 questions per screen (see screen shots below).

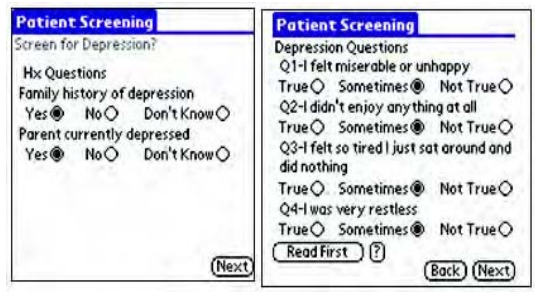

Figure 1 - Screen shots of application

The algorithm for the application is shown in Figure 2:

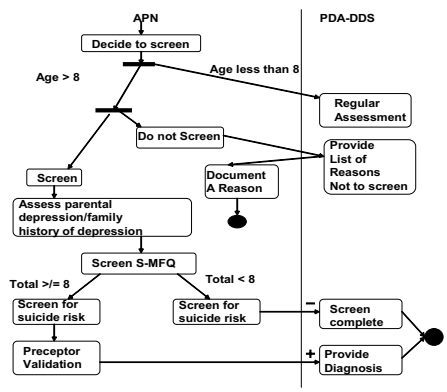

Figure 2 - Application algorithm

Usage

A total of 25 students were randomized into depression screening with 8 being fourth semester students and 17 being first semester student. In the fourth semester group, all students screened at least one child or adolescent for depression with an overall screening rate of 44.2%. The first semester students' overall screening rate was 37% with 23.5% doing no screening for depression. Students who failed to screen tended to be in specialty sites, ED follow-up clinic, or in private practices.

Of the 376 encounters eligible for pediatric depression screening, only one third (n=124) were screened for depression. If the student did not screen the child, they documented reasons for not screening. Over 81% cited other and about 8% noted a medical emergency as a reason for not screening. The remaining reasons included retardation (3.2%), learning disability (2.7%), patient refusal (2%), agitation (1.2%), other cognitive disorder (1.1%), and amnesic disorder (0.8%). Further explanation of the reasons for not screening in the other category is discussed in the qualitative data analysis.

Sociodemographic characteristics of patients in encounters in which screening versus no screening are shown in Table 1. Almost 80% of those screened were either Hispanic or Black.

Table 1 - Sociodemographic Characteristics in Screened vs. Not Screened (n=376)

	% Screened	% Not Screened
Ethnicity		
Hispanic	63.1	59.7
Black, not Hispanic origin	16.3	25.8
Asian or Pacific Islander	2.4	3.2
White, not of Hispanic origin	17.1	10.5
Other or unknown	1.1	0.8
American Indian or Alaska Native	0	0
Sex		
Female	51.6	52.4
Male	48.4	47.6
Age		
8-10	27.4	11.3
11-19	72.6	88.7

Overall, 20% of the patients screened were at risk for a mood disorder with 4% having a risk for a mood disorder and suicide. In the group at risk for a mood disorder, mean age was 13.1 years and 18.2% of patients were between 8-10 years. This was similar to the 13.4 years in the group at risk for suicide and a mood disorder. The latter group was totally female. No one screened was positive for suicide and negative for a mood disorder.

Within the group at risk for mood disorder, 35.3% had a family history of depression while 50% of those at risk for a mood disorder and suicide had a positive family history.

In terms of associated diagnoses, those identified as at risk of mood disorder had also had a high incidence of a psychiatric, behavioral or developmental disorders (n=44). The diagnoses with highest frequency were Attention Deficit Hyperactivity Disorder (ADHD), violence risk, and coping impairment. In the group at risk for a mood disorder, 68.2% had a behavioral or developmental disorder and only 31.8% had a diagnosis consistent with a physical disorder. However, of 467 diagnoses listed in the group not screened not screened for depression, only 6.6% had a psychiatric, behavioral, or developmental disorder diagnosis. The diagnosis with the highest frequency in the not screened group was well child (8.4%).

Focus group

Focus group discussions enabled exploration of students' knowledge, attitudes and beliefs about depression, depression screening, and the PDA-DSS. The major themes extracted for each of these areas are described in the following paragraphs.

Knowledge. Three main themes emerged during the focus groups: (1) limited, but some exposure to the problem of pediatric depression, (2) lack of a protocol within clinical site, and (3) lack of preceptor knowledge and support for depression screening. Many of the preceptors were not familiar or desirous of initiating screening.

Attitudes about depression screening. There were five related patterns centering on the theme of support that emerged during the focus groups. The students were concerned about a lack of time, knowledge, referral sources, comfort, and preceptor experience. The students expressed their need for more support from the site, preceptor, referral system, appointment system, and educational system to improve their knowledge base and comfort levels. The student felt it was inappropriate to do screening in emergency rooms or specialty clinics and wanted screening in primary care sites.

There was also a use and usability theme related explicitly to the PDA-DSS. Most students felt it interfered with the therapeutic relationship by creating a barrier between the patient and the student. One student commented, "The screening did not stimulate discussion. When I am done, there is not a transitional step." In terms of suicide screening, there was a similar theme of support. The students identified discomfort and apprehension regarding a positive screen. "You can ask the questions, but you must know what your next step is."

There were also cultural concerns raised since the students raised the issue of whether or not the patients felt comfortable with the idea of sharing their feeling. One student who was in a practice of recent Chinese immigrants commented, "Talking about feelings is not acceptable in this population."

Beliefs about barriers and benefits of depression screening. There was a discrepancy about the students' beliefs about depression screening and the barriers to depressions. Table 2 summarizes the themes identified.

Table 2 - Barriers and Benefits to PDA-Based Depression Screening

Benefits	*Barriers*
Prevent suicide *Enables sharing of feelings* *Opportunity to give holistic care* *Helps to pick up depression* *Improved quality of care*	*Time* *Perceived/real lack of referral resources* *Lack of preceptor knowledge and support* *Lack of knowledge of interventions* *PDA format* *Student discomfort with screening* *Cultural barriers*

Discussion

Clearly, there is a discrepancy between what the students believe are the benefits and their actual behaviors. Even though the students felt that screening should take place in a well visit, in 8.4% of the encounters in which no screening occurred, the diagnosis was a well child. In addition, only one third of eligible children or adolescents were screened. While recognizing that depression needed to be identified, the barriers overpowered the benefits. It is not clear whether the difference in the behavioral, develop-

mental, psychiatric diagnoses was a result of the greater awareness of the behavioral problems brought out by the depression screening or whether these children were presented with behavioral problems, cueing the students to screen.

This study has educational, clinical, and research implications. First, the students need to be empowered to intervene in children at risk for a mood disorder. Although teaching and counseling interventions are included in the PDA-DSS, students need further education about developing a therapeutic relationship and intervening with a single encounter. Educating preceptors about depression screening and interventions in a variety of settings may also promote screening.

The students need to improve their use of the PDA in clinical settings through strategies such as sharing the PDA screening with patients and entering initial information before entering the room.

Further research is needed to explore the patient's reactions to the PDA-based depression screening. It would also be important to compare different cultural group's reaction to the depression screening tools in paper versus PDA format. Further research is needed to assess whether the identification of depression helps students to identify other behavioral, developmental or psychiatric issues.

Conclusion

The data support that risk for mood disorder is fairly common in the population of primarily Hispanic and Black children and adolescents screened using the PDA-DSS and that there are missed opportunities for depression screening in a variety of settings. There are site, preceptor/student, and usability issues preventing depression screening. The organizational challenges are particularly difficult because APN students practice in different clinical sites with different resources and protocols. Since pediatric depression screening is relatively new, even experienced preceptors may lack the education to be effective primary contacts for the screening and identification of children at risk for a mood disorder or suicide.

Informatics innovations cannot be effectively implemented in practice without understanding the context of use. The triangulation of quantitative and qualitative methods was useful in helping the research team understand the screening behavior of students using the PDA-DSS and the associated organizational barriers in clinical settings. Moreover, these data provide direction for curricular changes and communication with preceptors regarding the use of the PDA-DSS.

Acknowledgments

Data Mining Results from an Electronic Clinical Log for Nurse Practitioner Students

Patricia Trangenstein[a], Elizabeth Weiner[a], Jeffry Gordon[a], Ryan McNew[a]

[a] *Frist Nursing Informatics Center, School of Nursing, Vanderbilt University, Nashville, TN, USA*

Abstract

Traditional techniques for collecting data on clinical experiences have been greatly flawed. Data cannot be easily collected in real time to make programmatic or placement changes "on the fly". Furthermore, it is difficult to look at data across students, specialty areas, and years because the data is typically not in a digital format. In response to this problem, the Vanderbilt University School of Nursing has created a web/PDA based clinical log to document the kinds of clinical experiences the students are having. Since our initial report, three years ago, we have collected three years worth of data, over 220,000 different patient encounters. This past year the data has been very complete, giving a full picture of the types of experiences the students are having. Our faculty have begun to analyze the data in the clinical log to examine the kind of experiences the students are having and to make programmatic changes and placement adjustments in real time. In general, the results supported that students in the various specialties managed patients and performed services appropriate to their specialty. Patients varied in ages, ethnic groups, payment sources, and medical diagnoses. Students did progress from an observer role to a more independent role in either a linear fashion or in a more biphasic mode with an increase in the observer role at the start of a new semester

Introduction

Traditional clinical education of nurse practitioner (NP) students has used preceptors for direct clinical supervision with faculty responsible for student progression, student evaluation and attainment of course objectives as well as curriculum revision. Nursing faculty collected data from nurse practitioner students to document their clinical experiences via on-site evaluation, discussions with the preceptor, paper logs and scan sheets completed at selected intervals during the course of study. These models led to a significant delay in receiving the information from students and providing appropriate feedback. In addition, it was very difficult to aggregate this data for a given student, or across students for a given semester or program because of the non-digital nature of the media Furthermore, it was difficult for students to examine their practice over time and for faculty to create reports and track student's progress.

A real-time method of data collection and analysis would allow for changes during, rather than after, the semester of clinical practicum. Faculty also thought that it was appropriate to map current evaluation methods against competencies being developed by the various specialty groups as well as the National Organization of Nurse Practitioner Faculty (NONPF). In short, the faculty wanted to re-design their clinical evaluation tool for the students in their specialty while preserving the ability to make comparisons across specialties in an aggregate format for purposes of accreditation.

A review of the literature revealed a scarcity of information with only one article describing the content and quality of a precepted clinical experience for nurse practitioner students. [1] As a result, the informatics team was invited to work with the specialty directors in the design, implementation, and evaluation of an online web based clinical log with PDA data input capabilities.

Methods

In 2004 VUSN began implementing an electronic (web/ PDA based) clinical log for nurse practitioner students. By 2006, the clinical log had been used by 200 students per year in seven different nurse practitioner programs for the entire length of their clinical experience. This article presents the results from the analysis of over 89,000 records collected during this past academic year. The implications for nurse practitioner education, curriculum revision, and student clinical portfolios for future employment are substantial. Not only was the log data used for program evaluation through data mining techniques, the students also used the log to create an electronic portfolio of their experiences and have, in some cases, secured employment as a direct result of their log entries.

Description of the system

The electronic clinical log was initially designed for data entry through the web. However, students raised the issue that they were entering data twice (once on paper patient side and again that evening as they transferred the data to

the log) a PDA interface was designed in response to their concerns. Students were instructed to synch their PDA with their desktops every night to avoid data loss. They were further instructed to upload their data once each week to the server based database. The records in the database were accessible via a web browser by students, faculty, and preceptors. The students could see only their own data, faculty and preceptors could see their students' data. Data collected included patient's age, gender and ethnicity; type of insurance, services rendered (professionally recognized criteria designed by the National Organization of Nurse Practitioner Faculty (NONPF)), ICD9 or DSM-IV codes and self assessment of the student's responsibility in patient management. Students and faculty could view the records and export logs to a spreadsheet for aggregation and graphing. Because of the unique nature of the Psychiatric/Mental Health Nurse Practitioner program, the PDA component for this specialty will be discontinued. Instead, next year, the PDA will be used to actually audio record the patient encounter, uploaded to the log, and made available for listening and comment by the faculty member or preceptor.

All electronic clinical logs (N = 114,206) collected during the entire year of study were subjected to data cleaning prior to analysis. If a student did not have data for the entire program of study all their records were eliminated in this analysis. After data cleaning a total of 89,401client encounters for 200 students remained for the purpose of this study. SPSS was used for all an analyses.

Results

Each time a student interacted with a patient it was treated as a single encounter. Therefore, if the student saw the same patient multiple times, as is common in the Psychiatric/Mental Health Nurse Practitioner specialty, each visit counted as one encounter.

The total number of patient encounters per nurse practitioner program was astounding and ranged from 2,072 for Pediatric Acute Care Nurse Practitioner students (PNPAC) to 34,700 for Family Nurse Practitioner (FNP). On average, the data showed there were 10 cases per week for each Acute Care Nurse Practitioner student and 21.4 cases per week for each Family Nurse Practitioner student. The mean number of encounters per student ranged from a low of 250 for the entire year for Acute Care Nurse Practitioner students to a high of 550 for Nurse Midwifery students. It should be noted that most of the specialties have an 8 month clinical rotation; however, the Nurse Midwifery program had a 13 month clinical experience. In general, Acute Care Nurse Practitioner, Pediatric Acute Care Nurse Practitioner and Psychiatric/Mental Health Nurse Practitioner students had fewer patients but longer encounters.

Acute Care Nurse Practitioner students and Adult Nurse Practitioner students (ANP) students saw older patients with a mean age of 55 while students in the Family Nurse Practitioner (FNP), Nurse Midwifery and Psychiatric/Mental Health Nurse Practitioner (PMHNP) programs saw middle aged patients (average age = mid 20's to early 30's). Students in all programs saw an almost equal percentage of males versus females except for Family Nurse Practitioner (FNP) and Psychiatric/Mental Health Nurse Practitioner (PMHNP) students who saw almost twice as many females as males, and of course the Nurse Midwifery students saw only female patients.

While the nurse practitioner students in all programs cared for many ethnic groups, the majority of the patients were Caucasian (49 – 84 percent across all programs), African Americans (11-24 percent across all programs) or Hispanic (1.5 – 24 percent across all programs). The majority of patient seen by Adult Nurse Practitioner (ANP) and Acute Care Nurse Practitioner (ACNP) students used either Medicare or private insurance as their source of payment, while the majority of patients seen by Family Nurse Practitioner (FNP), Nurse Midwifery, Pediatric Nurse Practitioner (PNP) and Pediatric Acute Care Nurse Practitioner (PNPAC) students had private insurance or TennCare (replacement for the state of Tennessee's Medicaid program).

The log allowed the students to enter up to four ICD9 codes per record. DSM codes were supported for the PMHNP students. Tables 1-3 describe the top ranking ICD9 or DSM-IV codes for student encounters across programs. While there were some similarities, the data revealed that students were caring for patients that were appropriate for their specialty. For example, Acute Care Nurse Practitioner (ACNP) students managed more CHF patients, and a significant portion of the Family Nurse Practitioner (FNP) students encounters were routine infant or child health checks.

Table 1 - Rank order of ICD-9 Codes for ACNP, ANP and FNP

ICD-9	ANP	ACNP	FNP
250, Diabetes	1	2	3
401, Essential HTN	2	5	
401.1, Benign essential HTN	3	1	1
272.4, Other hyperlipidemia,	4	3	
272, Disorders of lipoid metabolism	5		
428, Heart failure,		4	
401.9, Unspecified essential HTN			2
V20.2, Rout infant or child health check			4
477.9, 461.9 Allergic rhinitis or sinusitis, 465.9, Acute URI			5

Table 2 - Rank order of ICD-9 Codes for NMW and PNP

ICD-9 Codes	NMW	PNP
V22.1, Supervision of other normal pregnancy	1	
V22.2, Pregnant state, incidental	2	
V20.2, Routine infant or child health check		1
465.9, Acute upper respiratory infections of unspecified site		2
382.9, Unspecified otitis media		3
460, Acute nasopharyngitis [common cold]		4

Table 3: Rank order of DSM-IV codes for PMHNP students

DSM-IV Codes	Rank Order
296.9Mood disorder	1
309.81PTSD	2
314.01 ADHD combined subtype	3.5
296.33 Major depression without Psychotic features	3.5
296.8Bipolar	5
304.8 Polysubstance Dependence	6

The faculty members were also interested in the types of services their students provided to their patients. The services rendered were derived from the NONPF content competencies and were customized by specialty. Only those programs with some commonality with other specialties were reported here.

Acute Care students (ACNP and PNPAC) provided an average of 10 services per encounter while primary care student provided an average of 3 services per encounter. Tables 4 and 5 describe the highest ranking services provided as a percentage of the encounters. For example, Acute Care Nurse Practitioner

(ACNP) students identified and documented actual patient problems almost 72% of the time while Pediatric Acute Care Nurse Practitioner (PNPAC) students provided patient and family education nearly 80% of the time.

Table 4 – Types of service rendered as a percentage of encounters for acute care specialties

Services Rendered	ACNP	PNPAC
ID & documented actual pt prob	71.9	68.3
Analyzed all pharmacological agents	68.9	53.1
Collaborated with others	65.4	69.6
Obtained a H&P	63.8	58.9
ID & documented potential pt prob	57.7	63.9
Provided pt and family education	56.0	79.5
Developed an individualized Rx plan	54.4	69.5
Documented H&P	52.5	58.5
ID expected outcomes ind'l to the pt	51.2	59.2
Developed & documented list of differential diagnoses	48.5	57.6
Utilized evidence based practice	47.7	52.4
Documented ongoing eval of Rx plan		55.2

Table 5 – Types of service rendered as a percentage of encounters for primary care specialties

Services Rendered	ANP	FNP	PNP
Focused/episodic exam	84.6	85.7	68.3
Prescription	66.0	73.3	37.7
Health Education	47.6	71.9	55.7
Labs	45.0	35.6	18.5
Complete H&P			34.1
Developmental screening			25.2

The faculty members also wanted to evaluate the level of a student's responsibility in patient management, increasing from observational roles in early clinical experiences to more independent roles later in their clinical experiences. The student responsibility ranged from Observer, to Novice, to Beginner, to Advanced Beginner and had descriptors associated with each level for reliability purposes. Most of the students' clinical experiences transpired over two semesters. In order to determine if there was a natural progression from observer to more independent roles, the date of the encounter was converted to the month of the year indicating a progression in clinical experiences.

Correlations between students' responsibilities and the month were statistically significant for all of the programs at the .001 level. The correlations ranged from .192 for the Pediatric Nurse Practitioner (PNP) students to .396 for the Acute Care Nurse Practitioner (ACNP) students indicating that students did indeed progress from observer to advanced beginner during their clinical experiences.

While the correlations were statistically significant, they were low, indicating significant variability. In order to visualize where the variability existed histograms were constructed for each of the specialties. Figures 1 and 2 indicate two different paths from observer to advanced beginner that were noted.

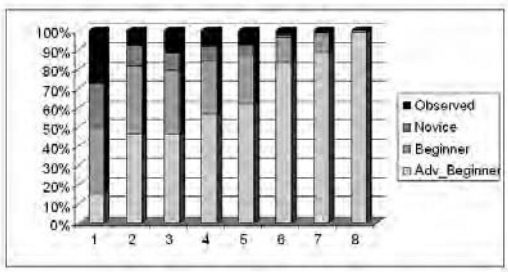

Figure 1 - Histogram of FNP students' responsibility by month of clinical experience

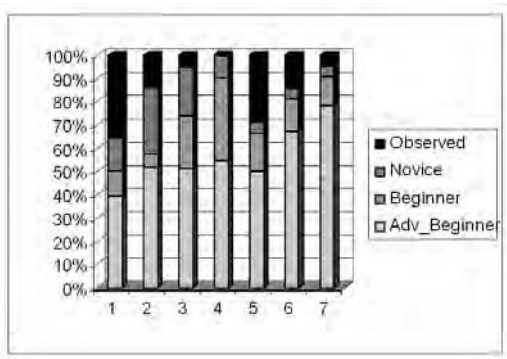

Figure 2 - Histogram of PNPAC students' responsibility by month of clinical experience

As can be seen from these two figures, the Family Nurse Practitioner (FNP) students showed a more orderly progression from observer to advanced beginner. On the other hand, the Pediatric Acute Care Nurse Practitioner students (PNPAC) students showed a more biphasic progression with an increase in the observer role in the fifth month. This corresponded to the beginning of a new semester and may reflect a change in preceptors, sites or performance expectations with the introduction of new skills. In any case, the faculty of the Pediatric Acute Care Nurse Practitioner students (PNPAC) program will look at the data to see if this trend continues and needs to be addressed or if it was an anomaly.

Discussion

NP faculty members have the ultimate responsibility for the supervision and evaluation of nurse practitioner students and for oversight of the clinical learning environment. [2] It is their responsibility to develop, evaluate and revise NP curricula. Students wish to secure the most favorable position possible and wish to make their case for such placement using data and evidence collect through the log. The NP faculty at the Vanderbilt University School of Nursing (VUSN) in conjunction with members of the Frist Nursing Informatics Center and with significant student input, developed electronic clinical logs (ECLS) for seven different nurse practitioner programs. Data presented represent a full program of clinical experiences for the students.

In general, the results supported that students in the various specialties managed patients and performed services appropriate to their specialty. Patients varied in ages, ethnic groups, payment sources, and medical diagnoses. Students did progress from an observer role to a more independent role in either a linear fashion or in a more biphasic mode with an increase in the observer role at the start of a new semester.

Conclusions

This article demonstrated the effectiveness of an electronic clinical log (ECL) for documenting the content and quality of a precepted clinical experience for NP students. Students entered data either by uploading from their PDA or by completing a web-based form. The records in the database were accessible via the internet by students, faculty, and preceptors. Data collected included patient's age, gender and ethnicity; type of insurance, services rendered (professionally recognized criteria designed by the National Organization of Nurse Practitioner Faculty (NONPF), ICD9 or DSM-IV codes and self assessment of the student's responsibility in patient management. Students and faculty could view the records and export logs to a spreadsheet for aggregation and graphing. Using informatics tools over 89,000 patient encounters for 200 NP students were analyzed.

Proposed revisions of the electronic clinical log (ECL) would include the creation of report dashboards to allow faculty members to determine "on the fly" whether the clinical experience was providing the right environment for the student. This would allow the faculty member to discuss with a preceptor the type of experiences the student was participating in as well as the quality of work the student was demonstrating. Currently a running total of the number of clinical hours has been well received by both students and faculty as a first piece of a dashboard. Given the volume of patient encounters the entire dashboard process would need to be automated with inadequacy flags automatically sent to the faculty member. We also plan on exploring the ICD9 data in detail to generate a culled-down list that would be more manageable for the students. We believe this shorter list will be far more useful to the

students who won't have to query through over 14,000 ICD-9 different codes.

Students have used the data to create a "clinical portfolio" listing their skills and activities across all of their clinical practice sites in their educational program and have analyzed their data using Excel. These advanced practice nurses will be participating in research and data collection/ analysis throughout their careers. A major benefit of our approach was that these students learned how to use Excel and demonstrated spreadsheet analysis techniques. The faculty were pleased that their students were as proficient with Excel as they are with Word.

An ECL will allow faculty to individualize learning based on the identification of gaps in the student's clinical experience. Faculty members can track the student's progress and types of patients seen. Data from the ECL can also be used to modify the curricula and provide documentation for grants and accreditation.

Phase I Implementation of an Academic Medical Record for Integrating Information Management Competencies into a Nursing Curriculum

Carole A. Gassert, PhD, RN[a], Katherine A. Sward, MS, RN[a]

[a] *University of Utah School of Nursing, Salt Lake City, UT, U.S.A.*

Abstract

This paper is the report of the first phase of a case study from the University of Utah to help students and faculty integrate electronic information management into the nursing curriculum. Cerner AES, a live-production clinical information system with an academic overlay, has been implemented into the first semester of an undergraduate nursing program. A consortium of schools that use Cerner AES collaborate in the design and implementation of forms used by students. The consortium also allows members to share strategies for using the system. By using the system students are developing needed informatics competencies for beginning level nurses. The paper discusses the implementation strategies used and initial results of this project. Plans for expanding the project throughout the nursing curriculum are also presented.

Keywords:

electronic health record, nursing education, nursing informatics competencies, clinical information system, simulation

Introduction

Sustainable development can be defined as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" [1]. This concept has been adapted in the context of health care to define the capacity of a health system to continue over time without major interruptions [2].

Basic resources of sustainable health systems include data and knowledge, and the skills of the health workforce. Improving the safety, quality, and efficiency of health care systems requires ubiquitous access to complete patient information and decision support—that is, electronic health systems [3].

Information has become a capital good [4]. Nurses and other health professionals need skills that will allow them to more effectively manage information technologies. These skills must be learned from the beginning, during professional education [3, 5]. Staggers, Gassert & Curran [6, 7] identified information management competencies for nurses at multiple levels of practice. Despite recommendations by federal agencies that informatics content needs to be included in nursing curricula, information and information technology competencies have been slow to become part of the nursing curriculum [8] and many nurses may not be adequately prepared to manage information using technology [4, 9, 10]. A recent study of university students found that students' self-reports of information management activities were not an accurate predictor of their actual health information competencies [11]. Information management competencies should be assessed by observing actual use of an information system. Education regarding health information management should be conducted in the context of "real-world" applications and behaviors; that is, in the information environment where clinicians work, and should incorporate concepts such as confidentiality, systems thinking, and knowledge-resource evaluation [12].

One initiative that aims to increase the use of technology in nursing is the TIGER (Technology Informatics Guiding Education Reform) initiative [13]. This initiative, spearheaded by nursing and informatics leaders in the United States, has developed a 3-year plan to integrate informatics seamlessly into nursing.

Materials and methods

This paper describes the first phase of a case report at the University of Utah to incorporate information management competencies throughout the nursing curriculum by using a live-production application that simulates a clinical information system titled UCARE AES. The acronym stands for Utah Clinical Academic Record Excellence and is the name of the Cerner Academic Education Solution system installed for use in first semester undergraduate courses in May 2006. This on-going project is used to introduce curricular changes necessary to ensure that nursing students are adequately prepared to contribute to sustainable health systems. UCARE AES enables faculty to address many of the informatics competencies needed for beginning nurses identified by Staggers, Gassert, and Curran in their work. Examples of beginning level competencies that are taught in first semester undergraduate courses using UCARE AES are presented in Table 1.

Table 1 - Examples of beginning level competencies obtained through UCARE AES

Competency	Activity Example
Uses administrative applications for practice management	Searches for patient Retrieves demographics
Uses sources of data that relate to practice and care	Locate "patient data" in UCARE AES
Accesses, enters, and retrieves data for patient care	Charts on class activities in UCARE AES Creates plans of care in UCARE AES
Uses an application to document patient care	Uses UCARE AES to document results of class activities and simulated patients
Uses an application to plan care for patients to include discharge planning	Uses UCARE AES to document plan of care
Uses networks to navigate systems	Uses UCARE AES (hosted remotely)
Describes patients' rights as they pertain to computerized information management	Learns HIPAA regulations through UCARE AES
Identifies basic components of the current information system	Knows components of UCARE AES

Cerner academic education solution

An academic version of an electronic medical record is available through Cerner Academic Education Solution (AES), an application that simulates a clinical information system using Cerner's PowerChart. AES has an academic overlay that provides students with prompts and evidence-based practice information as they learn to document assessments and simulated patient events.

AES was first introduced at Kansas University [14, 15] and later at University of Missouri-Kansas City. With the introduction of UCARE AES at University of Utah, the three schools have formed a consortium to share design and management ideas and issues about AES. The consortium is a great forum for exploring new ways to use AES. Although the three schools share a domain server and databases that are hosted at Cerner headquarters in Kansas City, each school has a unique username and established structure. Many forms are shared as each school contributes their wisdom to the AES development process. All three schools are evaluating student outcomes. Monthly virtual meetings, held to discuss ideas and issues, are chaired by Cerner personnel.

UCARE AES implementation

It is interesting that each of the schools in the consortium has implemented the AES system differently. At the University of Utah planning for the phased implementation began in January 2006. Undergraduate faculty responsible for teaching the first level concepts of nursing, patient assessment and clinical care courses met, in spite of weekly snow storms, with the undergraduate program director and two informatics faculty in charge of the Cerner project to form an implementation team. The weekly meetings were held in a room that allowed access to and visualization of Cerner AES with an overhead projector. Minutes recorded decisions made by the team for later reference. The first task was for the entire implementation team to learn about AES and plan the structure for Utah. The team selected the name UCARE AES for the system and Swoopes Medical Center for our username. Units in the medical center were named for the focus of the semester, e.g., medical-surgical 1, medical-surgical 2, pediatrics, maternity, etc. and are created to accommodate the number of clinical groups assigned to the semester. For example, there are nine clinical groups in first semester so units Medical-surgical 1A through Medical-surgical 1I were developed. Students are then admitted as patients to their assigned "unit" and given a password to access the system.

To help students and faculty become more familiar with UCARE AES a number of "play patients" were admitted to the Utah Start Unit. Nicknamed the "Olympians" because their fictitious names reflect Olympic events, UCARE AES users were encouraged to chart anything on these patients, whether it made sense medically or not. Case studies for student use during the semester were created and admitted to a folder titled "UCARE 1." These patients were "off limits" for charting. When the semester began students located information needed for their assignments from the case studies, they charted the information requested on themselves as patients. To help students learn the principles of data security and confidentiality, they are warned that faculty could track where they have been on the system and if they are looking at fellow students charting.

Forms needed by students to complete their assignments were moved from the large repository of forms maintained by Cerner to specific folders designated by faculty in the first semester. They chose to have 5 folders – assessment, patient care, plan of care, clinical prep, and competencies. Most activities required forms from the first three folders. To make it easier for students to find needed forms, the Course Coordinator for the clinical course in first semester included instructions in her course syllabus. Examples are listed here:

Document the following on UCARE AES

- Vital signs: Located in Assessment Folder/Adult Vital Signs
- Results of incentive spirometer use: Located in Assessment Folder/Adult Respiratory Assessment/Incentive Spirometer (Left margin)
- Pulse oximeter results: Located in Patient Care Folder/Adult Vital Signs
- Teaching patient to TCDB: Located in Patient Care Folder/Adult Vital Sign/Oxygen Therapy/Document under "other."

- Use of O2: Located in Patient Care Folder/Adult Vital Signs

To allow the system built to be completed by Cerner in a timely manner, all design development was completed by mid-April for the May 15th go-live. First semester students and faculty were oriented to UCARE AES on the go-live day. Base-line data for first semester students' experience with and knowledge about information systems was collected at their orientation.

The system was implemented with accelerated baccalaureate students (students who hold a baccalaureate degree in another field and wish to become nurses) on their first day of clinical classes. Implementation team members and Cerner representatives were available during the first two days of clinical classes to help students sign onto the system and chart information required for class. The only problems encountered during the go-live were related to student IDs entered into the system, all problems were quickly resolved. Assistance was available in the Computer Lab to work with faculty and students as needed. During the planning phase, some faculty became champions for UCARE AES and were an essential part of the successful implementation of the system. It is also important to note that we had the full support of the Dean of the College of Nursing for implementing UCARE AES.

Since the implementation team is quite small, a decision was made to implement UCARE AES one semester at a time. As soon as the go-live was completed, second semester faculty responsible for clinical courses were asked to join the implementation team to plan for Phase II of the implementation. The plan is to have all four undergraduate semesters implemented by May 2007. Therefore, UCARE AES will have been implemented in the entire undergraduate curriculum in 13-14 months, an ambitious plan.

Results

Phase I student and faculty response

During the planning for implementing Phase I of UCARE AES, first semester faculty decided to tie the learning activities of the three courses more closely together. Timing of content was adjusted so students were learning the same concepts in all three classes. Faculty also began to standardize language used to teach concepts to students. During the design work, only one new form was created and one form was revised. Consortium members adopted the form that was developed for Utah. It seems that schools can use forms designed for others and such action will standardize some of the language used to teach concepts to undergraduate students across schools of nursing.

Data were collected at the beginning and end of the students' first semester. Data were also collected from the faculty at the end of the first semester. Specific data will be reported as aggregated data when more phases of the project have been completed. In general, faculty responses were mixed after the first semester of use; faculty reported feeling only moderately comfortable with how to use the UCARE system. Some faculty did not appear to grasp the purpose of learning to use an electronic record; with complaints about documenting on forms instead of free-text notes, and did not recognize the importance of teaching information management concepts, as reflected in comments such as "UCARE does not match the charting used at my clinical site". Other faculty recognized UCARE as a tool to teach information management, and commented that it was "easy to learn" and "an effective way to teach and learn terminology."

Our observations of nursing students concur with findings that student self-report of skills is likely not accurate. Incoming students rate their technology skills and knowledge as being low, and indicate they do not know how to find and manage information in an electronic health record, yet rate their information management skills as moderate. After one semester of use, the students reported higher technology skills and knowledge, and greater ability to find and manage information in an electronic record. However, these same first semester students also indicate that they want more guidance and direction with using the system.

The students were aware that their faculty were not yet comfortable with the system. Student comments were mixed, ranging from "busy work", "I don't get the point" and "it did not match the system at my clinical site"; to comments such as "Even though my clinical site has a different setup for their electronic records it still helped me" and "It was difficult at first to use not because of the system but because of my lack of nursing knowledge"; to comments such as "It was very cool to know about before starting clinical and to be able to say I know what to do - and how to get on and navigate the system."

Implementation status

The UCARE AES is an ongoing project that will eventually include undergraduate and graduate nursing, medicine and pharmacy students. Nursing is responsible for the initial design and has begun implementation at the undergraduate level. We recognize that repeated exposure is necessary to achieve a level of comfort with information systems and believe it will be crucial for both faculty and staff to continue regular interactions with the system; therefore we are incorporating use of the system into every semester of our undergraduate curriculum before moving into the graduate program with UCARE AES.

To date, it has been implemented into the curriculum for 3 (of 4) semesters of the undergraduate nursing program, although only Phase I is the focus of this paper. First semester students use UCARE AES to learn how to document individual "patient" assessments. Second semester students use the system to locate data in a medical record, synthesize information from multiple sources, and make clinical decisions based on the synthesized data. Third semester students currently use the system for pediatrics and maternity nursing. In pediatrics students assess scenarios on patient simulators (manikins) and obtain the "patient's" history from UCARE AES. In maternity students use UCARE AES to review a case study, prepare care plans, enter nursing orders, and practice reading fetal monitoring strips. All third semester students use a form

called SBAR (situation, background, assessment, and recommendation) to practice communication with nurse and physician providers. The implementation team is presently meeting with fourth semester faculty and mapping their curriculum to UCARE AES. As stated, all semesters of the undergraduate program will be live by May 2007.

Acute care nurse practitioner faculty are anxious to incorporate UCARE into their curriculum. They will be added as soon as the baccalaureate curriculum implementation is complete. For the nurse practitioner students, curricular content will be matched to the "experienced nurse" competencies of Staggers, Gassert, and Curran. The School of Pharmacy has already expressed a desire to be added to UCARE AES. The discussions with pharmacy are pointing to the use of collaborative and interdisciplinary case studies that focus on pharmacotherapeutics.

Faculty are becoming more comfortable using the system as their experience increases. In general, faculty are beginning to recognize the value of teaching electronic information management concepts and are continually verbalizing how they think they can expand the use of UCARE in their curriculum. To help faculty adopt more of their learning activities to UCARE AES, we anticipate adding an informatics student in the role of a teaching assistant (TA) to the implementation team to work with clinical teaching staff to assist them in using the system. The TA will also be available to work with students who may be uncomfortable using the system. Midway through the first semester we added a Systems Analysis position to the team. That individual helps to interface with Cerner to resolve any problems that arise and to request needed changes to the system.

Conclusions

Since UCARE AES has been added to the undergraduate curriculum it is clear that students are gaining competence in using information technology and in doing electronic data management. This will help with the development of sustainable health information systems. In addition undergraduate students are becoming aware of nursing informatics as a field and some have expressed interest in specialization in this area at the graduate level. We look forward to being able to report data that is being collected throughout the project as the remaining phases of the implementation are completed.

[a] *Results 4 Care, Amersfoort, the Netherlands*
[b] *Acquest Research, Development and Consulting, Koudekerk aan den Rijn, The Netherlands*
[c] *ROC van Twente, Enschede*

Abstract

The ROC van Twente offers nursing education at the diploma level (MBO), and is innovating the program to include a major /minor structure for education about care and technology. In order to achieve this, a new position was created: the Master Docent, Care and Technology. The task of the master docent includes development of education for nursing about technology, multidisciplinary cooperation, and service to health care institutions among others.

The first development concerns a module about electronic patient records, standards, and semantic interoperability for continuity of care. The module is delivered to nursing students and to students from the information technology department, who work jointly in 'development teams'.

This paper describes the background, the development of the educational material and program, and the core content of the module. The core content are the care information models that link clinical materials with health care information standards. The program has started end November 2006. At the Medinfo 2007 conference the results of the course for the first group of about 40 students will be presented.

Keywords:

health informatics education, HL7, vocabulary, standards, continuity of care, electronic patient records

Introduction

National infrastructures for health care information exchange present a challenge to clinicians to adopt many standards. However, clinicians usually did not get education about standards, and even in this age, the curricula of schools of health professionals usually do not include such topics in the overcrowded programs, despite the growing need for it.

Ageing populations and increasing numbers of people with chronic diseases change the focus of health care in such a way that the application of technology becomes essential. Example technologies applied include home care technology, video surveillance, smart homes, and information and communication technologies such as telehealth and electronic patient records (EPR). Increasingly, these technologies are integrated with each other, for instance based on internet standards. Thus, new kinds of healthcare emerge and for health care professionals there is an imperative to make sensible decisions about what technology to introduce in the care environment. The integration of technologies and the changes in health care delivery depend more and more on standardisation and quality assurance.

This paper discusses how this approach to development of electronic messages and EPR is chosen as the topic for nursing education and for the education of application developers. A new educational program is introduced in this area, currently offered by the school of nursing and the school of technology of the ROC van Twente (Regional Educational Centre of Twente).

Background

In the Netherlands, the activities of the National ICT institute for Health Care (www.nictiz.nl) [1] lead to the emergence of standards for electronic message exchange and development of electronic patient records [2]. The use of the EPR will be required by law in the near future. Thus there is a need for all health professions to learn using it, and to be able to support the development of EPR that address the clinician's needs.

The Netherlands have based their 'information for health care' strategy on the message paradigm, applying the international Health Level 7 version 3 (HL7 v3) standard for the safe exchange of patient information to authorized users via a national infrastructure. HL7 v3 has been used in about 20 projects now as a method to determine (clinical) user needs, modelling these needs, and implement clinical content in electronic messages. In addition, several vendors successfully base their electronic patient record systems on the HL7 v3 models.

A key part of the developments include the HL7 v3 messages for continuity of care: this is the care provision domain [3]. This care provision message is meant for referral, acceptance, record exchange, discharge summaries and so on. It is a generic structure covering a standard way to identify sender and receiver, the patient, the purpose of the message and the expression of supporting clinical data. Clinical details are expressed in the 'care statements' or 'clinical statements'. The care statements themselves can vary significantly, but the way they are

included in the message is consistent over different clinical domains. This has lead to the development of care information models [4, 5] that standardize clinical content in such a way it can be used and re-used in the HL7 v3 care provision messages [5]. The purpose of this approach is to realise semantic interoperability between health care information systems and technologies. Semantic interoperability is considered such that professionals receiving patient data electronically, clearly understand the meaning of the message and can adequately continue the required care.

The school of nursing in Twente is timely with this approach due to the fact that the Twente region is a national pilot for the electronic patient record [7]. Health care providers in this region have requested more education in the area of care and technology, specifically about the use of information and communication technology. The program described below has been developed with input from representatives of the health care providers. The program is considered a try out for both education within the school of nursing, and for continuing education of the existing nursing workforce. These students from the school of nursing of ROC van Twente will eventually work as nurses, but with additional knowledge and experiences with the EPR.

Design of the educational program

The master docent, care and technology

The ROC van Twente is positioned in the east of the Netherlands. Twente is the front runner for the national implementation of the Nictiz spearhead projects: the medication record and the general practitioner to general practitioner record exchange. Therefore there is a perfect situational context for education. Students will be confronted with the developments in their practical / clinical traineeships.

However, for a school of nursing it is difficult to gain immediate expertise to start participation. Therefore a new teacher role was established: the first master docent for diploma level education. The master docent has responsibilities to innovate the education, in this example about care and technology, to bring in knowledge and experience, in this example built up on many projects in health standards [7], to involve the teachers, in this example via a project team, and to deliver service to health care facilities in the Twente region. Service to health institutions is delivered for instance via participation in requirements gathering workshops and traineeships.

To start the developments, a choice was made to keep it simple in the beginning, but at the same time take an example technology that is innovative and that relates to the national and regional developments of information and communication technology in health care. Thus, semantic interoperability was chosen as the leading principle to start the developments. Health care agencies in the region agree that they require nurses with skills and knowledge to participate in development of patient record systems and messages.

The care and technology module

The student groups participating in the minor care and technology include about 25 students from the school of nursing and about 15 students of the application developers program of the school of technology of the ROC van Twente. The teacher team is a multidisciplinary team of nurse educators and information technology educators.

An overall goal for the module that started November 23 is that both student groups, each from their own perspective, understand the process of determination of information requirements, standardization and development and implementation of electronic patient record systems and electronic messages. The care information models are intended as a framework that bridges the often existing communication gap between system users and system developers.

The minor program serves as a differentiation within the nursing and within the technical education. Therefore it is assumed that students do know the basics of nursing care and have experiences in traineeships before entering the minor program. For the technical students, an equivalent background in systems life cycle and methods applied is expected.

Specific learning objectives / required competencies include:

- Multidisciplinary cooperation
- Communication and active participation
- Analysis of the need for care (nursing students)
- Analysis of information needs (application developers).
- Development of a care information model that includes purpose, description of variables, codes, HL7 v3 model, and technical data specification.
- Development of functional requirements for a electronic patient record system for continuity of care.

In total, the program consists of 12 weeks of education. A total of 4 contact hours per week is presented in small working groups with a mix of nursing and technology students. In addition, the students need an average of 4 hours a week for reading and preparation of the teamwork. The program is presented in Table 1.

The first five weeks are about the need for electronic patient records and messages, and the content of the messages. Then the application developers fall back on their normal program, and use time in between to work on the functional requirements and system design. In the meantime the nurse students have a clinical traineeship. For six of the nursing students, the traineeship involves participation in a nursing system development. In this particular setting, the ROC van Twente, a home care agency, and a vendor work together to create a new traineeship.

After about 16 weeks, both the nursing students and the application developers come back to school and continue another 7 weeks of education on this module. These 7 weeks deal with the subjects presented in Table 1. They include continuity of care and requirements for electronic patient records and messages. Further, the development of a care information model is a core element. The students

finish the program with a presentation of requirements, design and examples. Teaching materials include a module and reading materials, based on the work for the national information and communication infrastructure.

Software: stroke care record system

Another teaching tool is the electronic stroke care record system by Portavita [8]. Portavita is a vendor that agreed to have their software for stroke systems, still under development, made available for the students of ROC van Twente. This is a cost neutral arrangement, where both parties benefit: ROC van Twente gets access to a professional clinical information system for education, the vendor gets exposure and feedback on the system, and educational materials developed around the system become available for clients.

Table 1 – Overview of the program for Care and Technology

Week 1. The need for the electronic patient record (EPR) and standards.	
Getting acquainted with each other. Nurses: describe what nursing needs in the EPR. Technicians: support the nurses and apply methods for requirements gathering and functional design. Determine how to cooperate for 12 weeks.	
Week 2. Analyse information in care	
Nurses: explain which data are required in a stroke care record system. Technician: interview the nurses to get the requirements for a system.	
Week 3. Care information model 1	
Study the care information model structure and start with making one example. Nurses the clinical and terminology part, technicians the model and technical specification.	
Week 4. Care information model 2	
Develop a care information model, including clinical, terminology, HL7 v3 model and technical specifications.	
Traineeship intermezzo	
Nurse student	**ICT student**
Study the existing paper based methods for continuity of care during traineeship	Develop a functional design for a nursing record system
Week 5. Continuity of care for stroke	
Study needs for continuity of care and describe processes, professionals involved, roles, tasks and activities, **information** to be exchanged and apply UML modelling.	
Week 6. Continuity of care record	
Prepare a continuity of care record for stroke patients: contents, standards, sequence diagrams and functional design.	
Week 7. Review existing materials	
Select all relevant care information models from the repository www.zorginformatiemodel.nl	
Week 8. Classifications and codes	
Apply coding from standardised nursing and health vocabularies	
Week 9. Evaluate design against existing system	
Compare the functional design with existing system for stroke care	
Week 10. Functional Design	
Discuss the functional design Technology student presents to working group and makes final adjustments.	
Week 11. Preparation	
Prepare a presentation for the whole class and for teachers Criteria include: 1) Agenda and minutes, 2) Even distribution of the work in the small group, 3) The subject of the presentation has been negotiated with and approved by the teacher, 4) Apply presentation software, 5) Include the following: care information model, functional requirements, evaluation of group work, functional design	
Week 12. Final assignment	
Present as workgroup the results in public	
Evaluation	Evaluate the course and work

Care information models as a core topic

In order to have concrete materials available that are manageable for the students, the use of the care information models [5] is taken as the lead during the minor program. The care information models serve as a reusable building block within the framework of HL7 v3 Care Provision messages [2, 3, 5].

Care information models combine different standards materials and create valuable content for intelligent semantic interoperability [5]. They function as a communication bridge between clinicians and technicians and

facilitate inputs into the technical development of electronic messages and EPR systems.

The document structure for the care information models consists of meta-information, detailed description of the clinical instrument, and the reason for its application in practice [5]. It specifies clinical care using professional evidence, uses standardized terminology and coding, uses standard (HL7 v3) information models, and specify at the detailed level the technical requirements for the clinical content. Thus, the technical implementation according the HL7 v3 message and data specification are included via mapping tables, which are useful for EPR development as well. In most documents, one for every item of clinical activities, observation, or instruments, the current components include, in a recently revised format, the following components [5, 9]:

1. Version management and authorship
2. Explanatory introduction about the use of care information models
3. Aim of the instrument, index, scale, act, or observation
4. Scientific foundations / evidence base or other foundation such as guidelines
5. Description of variables / data items / values
6. Working instructions for practice
7. Interpretation guidelines for the results
8. Information on the topic relevant for care process
9. References / acknowledgements
10. An example of the instrument (when available)
11. HL7 v3 message model and description
12. Mapping table from domain to standardized terminology and to HL7 v3 domain message model
13. XML message example (extensible markup language)
14. Copyright issues, such as licensing of source materials, allowed use of care information models
15. Screen designs / screen shots for the instrument
16. Remarks, e.g. if a Dutch version is different from English version of an instrument
17. Contact information: how to contact the author(s)
18. Disclaimer

A current overview of the 90 care information models, in the earlier – less complete – format, is available at the website: www.zorginformatiemodel.nl. [4]

Students work together in small groups to complete one (draft version) of a clinical relevant topic and specify it according to the above format for the care information model and complete the HL7 v3 specification.

Exam

The exam of the module consists of a presentation by the students of the design of a system for continuity of care, based on the professional and information standards. Nursing students must underpin their requirements from a patient care perspective. Application development students must substantiate their part with the analysis, modelling and design of a system (component) that meets nurses' requirements.

Future plans

Currently the module is taught to the two student groups. However, once the module is delivered, more work for the master docent and the project group is waiting. The following new developments are on the agenda for 2007 and 2008.

1. ROC van Twente wants to integrate the module to other health care providers' educational programs.
2. The content and assignments will be put into an electronic learning environment, thus making it available to students wherever they are.
3. The minor program will be made available for continuing education for the health care agencies in the region Twente.
4. Other ROC's (diploma schools) have joined or will join and a wider spread of the materials and the education on these subjects is in preparation.

Discussion and conclusion

National and regional developments of information and communication technology in healthcare, such as electronic patient records and electronic messages, are emerging in order to deal with the changes in the health situation of the Dutch population. Due to results of standardisation efforts, useful materials become available for education. The ROC van Twente decided to develop a new role, the master – docent care and technology – to assist in establishing an innovative program for nursing students and technology students.

The innovation includes several challenging areas. The first is a new kind of content: the sensible use of technology in the care environment. Secondly, the application of clinical, vocabulary, message and technical standards for exchange of information for continuity of care, based on a well established format of care information models. Thirdly, the use of electronic record software for stroke patients currently under development. Fourth includes the multidisciplinary student groups: nurses and technical developers, handling the same problem each from their own perspective. Fifth, a minor program within the existing education, indeed with a traineeship for currently few nurse students with a focus on system development. Finally, a project group from teachers, representatives of health agencies, and experts working together to achieve this.

It is an exciting area of developments and we will be proud to present the results of the first course during the conference.

Acknowledgments

We want to thank the participation of all involved teachers and heads of departments of ROC van Twente, and the members of the project team from the health institutions in the Twente

Region. Nelleke Plaisir of Acquest for her contributions to the module and reading materials.

Abstract

Evaluation of Internet-delivered continuing education for health care providers requires appropriate consideration of their level of participation. To fully assess participation requires multidimensional measures, including factors such as the volume of participation (page views), frequency (visits), variety (components accessed by each provider), and duration (months of activity). We calculated crude and refined (adjusted for study design) measures and then compared these measures across three longitudinal Internet-delivered continuing education to health care providers (N = 429). We found that participation varied across study, varied by factor and varied by specific measure. Correlation between crude and refined measures within a factor and across factors differed significantly. Participation assessment of internet-delivered interventions varies by the selection of measure and factor. Further research assessing the potential for these measures to predict intervention effectiveness is needed.

Keywords:

internet, continuing education, educational measurement, quality of health care

Introduction

The Internet has promise as a new tool to increase translation of research into clinical practice.[1] If proven effective, low-intensity Internet-delivered continuing education interventions have a high potential for dissemination. These interventions seek to improve provider knowledge, motivation, and behavior and are often multi-modal with access to case-based education, decision support, and patient education materials. Many such interventions have the ultimate goal of improving quality and enhancing safety. Although evaluations of Internet-delivered continuing education for healthcare providers are increasing[2-8], no standard method of evaluating these interventions exists. To more fully understand the impact of these interventions, investigators need to measure participation, including tracking of all provider "encounters" with the program.

Tracking provider-intervention encounters, however, is challenging. Web tracking software most frequently tracks page views and visits.[9, 10] However, all page views may not be of equal value. A frequent goal of website developers is to create "stickiness" - a measure of repeat usage of the intervention.[11] Thus, investigators might want to assess frequency of use per month enrolled in a longitudinal intervention. A combination of measures may best represent actual participation.

Few previous studies of Internet-delivered continuing education have measured differences in participation. Also, it is unknown how different measures of participation are correlated. As a first step toward developing a scientific approach to measuring participation, we propose a four-dimensional model. The general factors include volume, frequency, variety of components accessed, and duration of access. Within this model, we developed crude and refined measures of each factor and then compared these measures using data from three longitudinal Internet-delivered continuing education interventions. Our goal was to determine how the measures varied by study and to assess the correlation of crude and refined measures within factor and across factor.

Methods

Study design

Our group is conducting three separate group-randomized trials of Internet-delivered educational interventions to improve practice patterns of health care providers. Funded by the U.S. National Institutes of Health (NIH) and Veterans Affairs Health Services Research & Development (VA), these trials have similar designs and objectives but different target populations of providers and disease foci. The National Heart, Lung and Blood Institute (NIH) MI-Plus, conducted in two southern states, and VA MI-Plus, a national study, are parallel interventions targeting different provider populations: Medicare primary care providers in two Southern states and clinic-based primary care VA providers, respectively. Both MI-Plus studies seek to improve care for ambulatory post-myocardial infarction patients with multiple co-morbidities. Funded by the National Institute on Drug Abuse (NIH) DentalTobaccoControl.net (DTC) targets dental providers and seeks to improve tobacco cessation practice patterns in dentistry.

We prospectively tracked participation by 429 healthcare providers enrolled in the intervention arms of these trials. Users (private practice physicians, nurse practitioners, physician assistants, dentists, and hygienists) were recruited to the websites through mailings, phone calls, and emails and enrolled over multiple months ranging

from six to twelve, depending on the study. For this analysis, tracking data for each study was collected through a specific calendar month in 2006 (March for NHLBI MI-Plus, August for VA MI-Plus, and September for DTC). As enrollment was rolling, total months of enrollment varied for individual providers (mean months of enrollment was 14 (SD 5) for NHLBI MI-Plus, 11 (SD 4) for VA MI-Plus, and 12 (SD 4) for DTC). Once enrolled, all providers received scheduled email reminders, including notifications of new content, to encourage participation. All providers received continuing education credits specific to their specialty (medical or dental) and a certificate of appreciation for their participation. Additional incentives were provided in the NHLBI MI-Plus study (access to online journals and a textbook) and VA MI-Plus (subscription to the *Medical Letter*). Each study was approved by the appropriate Institutional Review Board.

Intervention descriptions

The core of all three interventions was case-based educational programs using interactive, web-based modules with tailored feedback based on responses to questions. During the tracking periods, the content and number of cases varied by study (6 for MI-Plus, 8 for VA MI-Plus, and 3 for DTC). All three studies had an accompanying "toolbox" with practice tools and patient educational materials that could be downloaded. The two MI-Plus studies included 1) a literature watch segment updated at intervals with reviews of the literature and 2) a guidelines component with summaries of current guidelines applicable to post-myocardial infarction patients. The literature watch and guidelines of the MI-Plus studies were analogous to the headlines and library components of the DTC study. Feedback of performance data with peer comparisons was provided to NHLBI MI-Plus providers. In the DTC study, testimonials of provider's success in encouraging smoking cessation were included. For this analysis, we focused on intervention components that were consistent across the three studies.

User authentication was required for all providers as they logged onto the interventions. Thus, we used server tracking logs linked to visit to calculate the measures of participation. The log included an individual user identification number and was tagged with date and time.

Measures of participation

As noted above, we propose a four-dimensional model to evaluate participation. The four factors are 1) volume, 2) frequency, 3) variety of components accessed, and 4) the duration of activity. For each factor, we developed crude and refined measures for each factor. Volume measures included total number of page views (crude) and the refined measures (number of page views per visit and number of pages per month). Frequency measures included total number of visits (crude) and number of visits per month (refined). Variety measures included number of components accessed (crude). Because the central component of the three interventions was the cases, we also created variety measures specific for the cases: number of case modules completed (crude), and mean percent of case modules completed (refined). Duration measures included 1) number of months actively participating (crude), defined as months from first to last logon, and 2) mean percent of enrolled months (refined), defined as the proportion of enrolled time known to be active (months active/months enrolled) because of the variation in potential enrollment across studies. We defined five categories of providers (private practice physicians, VA physicians, VA nurse practitioners/physician assistants, dentists and hygienists).

Other measures of participation could be calculated. Specifically, our measures focused mostly on counts, not session time, or time per webpage. Using session time is challenging as our providers rarely logged off, but would simply close the site so that session time continued indefinitely. Also, frequent outliers for session time existed (over five hours of activity in a single visit) suggesting that providers would just leave the page open and go to another task. Thus, we have not used session time in this analysis.

Statistical analysis

We calculated the means and standard deviations of each measure. We assessed differences in participation measures by type of provider using t-tests. Because of the multiple comparisons, we chose a significance level of = 0.01. Then, we evaluated participation in each intervention component by provider group and assessed differences between provider groups using chi-square tests. Finally, using participants in all three studies, we assessed pair-wise correlations between measures within and across factors using Spearman's rank correlation coefficient. We then repeated this analysis for each individual study again with = 0.01.

Results

We recruited 429 providers from 344 practices. These included 108 private practice primary care physicians in the NHLBI MI-Plus study, 193 VA primary care providers (125 physicians and 68 physician assistants or nurse practitioners) in the VA MI-Plus study, and 128 private practice dental providers (68 dentists and 60 hygienists) in the DTC study. Across studies, the mean number of months since enrollment was 12.2 months (SD 4.5).

Results by study

Overall, across measures of volume, frequency, variety, and duration of participation, values tended to be higher for the VA providers, both physician and non-physician, compared with private practice physicians and dental providers (Table 1). The mean visits per month among VA physicians, 0.62 (SD 0.52), was twice that of private practice physicians, 0.29 (SD 0.22), P = 0.001; the mean visits per month for VA Nurse-practitioners/Physician Assistants was even higher, 0.85 (SD 1.5), compared with private practice physicians, P = 0.0002. The point estimate for page views per month was highest among dentists in the DTC study (19.5) but the standard deviation was quite wide (106.6), thus this estimate was not significantly different than the estimates amongst the other providers.

Variety of access as measured by number of components was lowest among the dental providers [1.5 (SD 1.2) for dentists and 0.97 (SD 0.89) for hygienists] compared with the other studies, but as measured by proportion of cases completed, participation in the DTC study was similar to the VA MI-Plus study. Duration of participation ranged from a mean of 7.9 months (SD 4.1) in NHLBI MI-Plus (the longest running study) to 2.8 months (SD 4.2) for hygienists.

Months from First to Last logon	7.9 (4.1) [c,d]	7.0 (5.4) [e,f]	6.2 (5.5)	4.8 (4.9)[c,e]	2.8 (4.2) [d,f]
Mean Percent of enrolled months	51%(38) [d]	56% (37) [e,f]	53 (40)%	39% (38) [e]	24% (35) [d,f]

* Participation measured in four dimensions – volume, frequency, variety, and duration of access. Cells in the same row with the same superscript are statistically significantly different, p<0.01
Crude measures, ‡ nurse practitioners and physician assistants
§ Percent of enrolled months = (Months for first to last logon/total months since enrollment)

When comparing use of individual intervention components, the VA providers had high participation, private practice physicians had moderate participation and dental providers had lower participation (Table 2). The VA physicians participated in a higher percentage of the cases (84%), compared with the private practice physicians (71%; P< 0.01) and the dentists (68%;P<0.01). Notably, a much larger proportion of VA physicians accessed literature watch than private practice physicians (82% vs 38%, P=0.01). Similar results were seen comparing the VA non-physicians with all other categories. The dental providers had the lowest rates of accessing each of the four factors.

Correlation of measures

The correlation between individual measures varied from strong (0.93) to weak (0.11) (Table 3). In general, "pages per visit" was the least correlated with the other measures. Also, the duration measures had a higher number of moderate or weak correlations with the volume, frequency, and variety measures. Within each of the four factors, correlations also varied. Some of the weakest within-factor correlations were again seen for measures of volume. The pattern of strength of the correlations seen in Table 3 was not qualitatively different when the analysis was repeated for each individual study (data not shown).

Discussion

To document the effectiveness of Internet-delivered educational interventions that seek to translate research into practice, we need more randomized trials. To fully evaluate these trials, investigators will need to describe the level of participation in the intervention as a surrogate for exposure. We evaluated a number of easily calculated measures of provider participation in Internet-delivered continuing education interventions for healthcare providers and noted three general patterns of variation – overall patterns by study, patterns across study by similar measures, and patterns of correlation among measures.

Table 2 - Participation in Individual Components by Provider Type in Three Internet-based Interventions

	Private Practice Physicians	VA Physicians	VA NP/PA*	Dentists	Hygienists
	N = 108	N = 125	N = 68	N = 68	N = 60
Any Interactive Case	71%	84% [e,f]	81%	68% [e]	63% [f]
Literature Watch or Headlines	38% [a,b,d]	82% [a,e,f]	75% [g,h]	32% [e,g,i]	6% [d,f,h,i]
Guidelines/Library	52% [c,d]	44% [e,f]	50% [h]	12% [c,e]	3% [f,h]
Toolbox	63% [d]	69% [e,f]	63% [g]	45% [e,i]	23% [d,f,i]

Cells in the same row with the same superscript are statistically significantly different, $p<0.01$
* nurse practitioners and physician assistants

Overall, the measures suggested varying rates of participation by study, with VA providers having the highest participation. This may be because VA providers have relatively greater computer access. It may also be related to "horizontal" use of technology. All VA providers in the community-based outpatient clinics use computers to access an electronic health record; thus, use of the computer for Internet-delivered continuing education during routine workflow may be more feasible and acceptable than in the private practice physician and dentist offices where use of the computer for other purposes likely has considerably wider variation.

We also found that the crude measures had more statistically significant differences across studies compared with the refined measures. Our refined measures included adjustment for variations at the study level to account for differences in exposure to the intervention. For example, number of months of enrollment varied across the studies. Thus, the total time available for participation varied considerably. Also, total number of pages was greater in the MI-Plus studies compared with the DTC study. Thus, the point estimate for total pages favored the physician groups but "pages per month" for dentists was higher although not statistically significantly so. Conceptually, we feel the refined measures are likely more appropriate when comparing participation across studies because they adjust for differences in the interventions and may provide a more accurate comparison across studies.

Third, we found that the correlation statistics varied comparing the various measures both within dimensions and across the dimensions of volume, frequency, variety, and duration of participation. "Pages per visit" had the weakest correlations with the other measures. Duration of participation showed only moderate correlation with the adjusted measure of visits per month and pages per visit.

These measures demonstrate both the successes of the three interventions and some difficulties. All three interventions successfully maintained provider participation over a number of months. However, participation did wane, with most providers only participating for around 50% (or less for the DTC study) of the total time available. In the DTC study, providers less frequently accessed the non-case intervention components. We have used this information to increase marketing emails encouraging current DTC study participants to access the toolbox and other intervention content. Our efforts to maintain participant

intervention activity had varying effects, with wide variations in participation of individual providers within studies. For some measures, the standard deviations were equal or greater than the point estimates. Future studies may require targeted marketing strategies to individual providers or smaller targeted groups to enhance participation. Also, working with individual practices to understand barriers to participation and to facilitate access may be required.

Each of our four factors has some face validity, the measures demonstrate within study variation, and we have demonstrated that the measures differ across studies. This suggests that our measures capture differences in level of participation, as intended. Still, further analyses are needed to fully assess the multi-factorial model of participation that we propose. Additional analyses evaluating factors that may be associated with participation (number of computers, acceptability of technology, computer literacy) should be conducted to assess whether participation can be predicted. Most important, analyses need to be conducted to assess whether these measures of participation predict outcomes including changes in knowledge and performance, and which measures are better predictors of outcomes.

Prior educational literature suggests that approaches that provide education in small content amounts separated by time ("spaced approach") are more effective than large content approaches. Thus, one might hypothesize that frequency and duration of participation are both critical. However, these factors cannot be considered in isolation, as one might have high frequency participation in the intervention with low volume and low variety. In prior research, a model for web surfing – the foraging model – suggests that there are discreet patterns of participation[12]. Thus, the four factors might be combined to categorize users into certain patterns of participation. We have not attempted to combine these measures into a single participation factor because we feel that further empiric validation of criterion validity is needed first.

A recent manuscript measuring participation in a patient website[13] noted that participation is but one measure of engagement and that participation should be considered in the context of satisfaction with content, assessments of knowledge, and process measures that may potentially lead to the desired endpoints. We feel this also holds for provider interventions. To fully predict endpoints, measures other than participation will also be needed.

Our study was limited in that data from only three interventions were available. As noted above, this is a first evaluation of these measures, and includes only correlational evidence, but additional assessment of construct and criterion validity are the object of ongoing research. Differences in participation across studies may be due to variations in interest, time availability, computer experience, and ease and type of computer access, none of which we could assess in this analysis.

Conclusion

In conclusion, participation of providers in Internet-delivered interventions varies widely across multiple dimensions of measurement. Primary and refined measures of volume, frequency, variety, and duration discriminated across studies. Within study variation of these measures was also high, as noted by the high standard deviations. In our studies, these measures have been used to track ongoing participation, suggest modifications to website design and marketing, and will be useful in understanding the outcomes of these interventions. Our preliminary analyses add to the prior literature by identifying categories of participation measures, and begin to approach the complexity of assessing participation. Much further research is needed to develop and validate the science of measuring participation for Internet-delivered continuing education.

Abstract

The present study investigates the knowledge, perceptions and attitudes of medical students in Sri Lanka in regard to e-health. We also examined the barriers which impede them to develop knowledge and skills in e-health within their medical curriculum. A questionnaire focusing on the knowledge, attitudes and expectations of medical students towards e-health was distributed to all final year students (n=136) at the Faculty of Medical Sciences, Sri Jayewardenepura University, Sri Lanka. Response rate was 74%. 43% of respondents stated that they were familiar with the term e-health. 51% rated their knowledge of e-health applications as minimal. 88% admitted that they had no e-health education or training of any kind. Over 80% of all respondents thought that e-health had an important role to play in the current and future health sector, particularly in developing countries. Our survey revealed that respondents had very poor access to computers and Internet use was rare. 77% of respondents admitted that they were not provided with systematic knowledge and skills in e-health through their medical curriculum and identified the absence of formal education in e-health as a serious shortcoming.

medical education, e-health, curriculum development, developing countries

Introduction

The healthcare industry in general is under growing pressure to provide services more efficiently and economically [1]. As far as developing countries are concerned, problems and issues associated with the health services are even more daunting [2]. Extreme poverty has prevented governments in developing countries from funding health adequately resulting poor state of health in the populations. Poor health infrastructure, inadequate facilities and the shortage of healthcare professionals are characteristic features of the health sector in developing countries. Rural and remote communities – where the majority of the population live in developing countries - are particularly deprived of health services. Addressing health issues in developing countries has become a global concern [3]. However, there is no quick remedy to health problems in developing countries as the improvement of health infrastructure and the increase of the number of health professionals require long-term investments and policy implementations [4].

In this context, e-health has been identified as one alternative to provide improved services and specialist care in developing countries [5]. The potential of e-health applications, i.e. the delivery of health services across a distance by using information and communication technologies (ICT) is being recognised for its potential, especially for the delivery of health services to rural and remote areas [6]. International organizations such as the United Nations (UN) and the World Health Organization (WHO) have acknowledged e-health as a potential alternative to address acute health needs in developing countries [7-8].

Among many other factors, the acceptance of e-health by health professionals is extremely important if this new modality of healthcare delivery is to become an integral part of mainstream healthcare. Knowledge, acceptance and enthusiasm to utilise e-health as an alternative way of service delivery by healthcare professionals, particularly by doctors would help facilitate the integration of e-health. Needless to say, developing countries are one of the most likely beneficiaries of e-health. Thus, knowledge and skills in e-health and keenness to use this tool by local healthcare professionals would undoubtedly help address at least some of the existing problems.

There is a growing body of literature showing that e-health has a role to play in contemporary healthcare [9-10]. Also literature is evident that e-health is useful for developing countries [11]. However, there is not many studies done to investigate the level of knowledge among health professionals [12]. A few studies show the level of IT knowledge in medical students [13].

Sri Lanka is a developing country according to number of indicators. Like other developing countries, health sector in Sri Lanka has been challenged by various problems. Total expenditure on health as a percentage of GDP in 2002 was 3.7% which is significantly lower than that is in

industrial countries. Overall access to health facilities for people in Sri Lanka is low. For example the number of hospital beds per 1000 population constitutes 2.9. The number physicians per 10,000 population is 4.11 [14].

Rural population in Sri Lanka constitutes 77% of the total population [15]. The most complete hospital facilities and highest concentration of physicians are in the urban areas, while many rural and remote areas suffer severe scarcity of health services. Thus the territorial disparity in health services is a characteristic feature in the island (Table 1). Emergency transport of patients especially in the countryside is still at a rudimentary level.

Table 1 - Number of medical specialists in urban and rural hospitals in Sri Lanka[1]

Speciality	Urban	Rural	Total

Aims

The objective of this present study was to evaluate the knowledge, attitudes and perceptions of medical students towards e-health since their preparedness is a key to the success in implementing e-health in developing countries.

Methods

We designed and distributed a survey to assess the knowledge and attitudes of medical students towards the broad subject of e-health. The survey was distributed to all final year medical students (136) studying at the Faculty of Medicine, Sri Jayewardenepura University (SJU), Sri Lanka. Questions were divided into the following sections: demographic details, knowledge in e-health, relevance to future practice, the use of computers and the Internet and access to e-health education.

Results

Demographics

A total of 100 (74%) students completed the survey. 54% of respondents were female. The majority of respondents (about 91%) were between the age of 26-30 years and the remainder were between 23-26 years of age.

Knowledge of e-health

Nearly half of all respondents (43%) admitted that they were familiar with the term e-health. However, 51% of respondents described their knowledge and skills related to e-health as minimal while 22% were unsure. 86% of respondents had had no exposure to e-health education and/or training. 71% of respondents said they had never read any literature on e-health.

Relevance of e-health

Questions were asked to examine the perceptions of the students about e-health. About 86% of all respondents admitted that e-health will have an important role to play in the current and future health sector. Only 2% disagreed with that statement while 11% were not sure. Again 86% of respondents agreed with the fact that e-health will be useful in their future practice. Only a very small number admitted that e-health will have no use in their future practice. 78% of respondents admitted that e-health applications will improve their services. Majority of respondents (77%) believed that e-health would have particular relevance to developing countries and 85% agreed that e-health should be encouraged.

Use of computers and the internet

Several questions were asked to establish the knowledge and skills of the participants in computing and the level of the Internet use. The results of the survey showed that the availability of computers and the Internet for students was low. They admitted that the access to computers and the Internet was limited both at home and at the university. Only a very small number (3%) of students had frequent access to computers and the Internet. The majority of students (65%) used the Internet very rarely. Nonetheless a large number of students admitted that they were comfortable using computers and the Internet. Also 67% admitted that they had formal computer education and training. The majority of students expressed the desire to have better and more frequent access to computers and the Internet.

Access to e-health education

41% of respondents admitted that they had received no satisfactory knowledge of e-health through their medical program while 36% were not sure. While 79% of respondents suggested that e-health should be included in the medical curriculum and 56% thought that e-health must be offered as an elective. About 85% of survey participants suggested that e-health course must include a practical component to provide hands-on skills. More than half of respondents (64%) expressed their willingness to study e-health at post-graduate level.

Participants of the survey also identified the lack of appropriate educational programs, financial constraints, lack of

sufficient access to technology and traditional methods of medical education as major barrier to develop systematic knowledge and skills in e-health.

Discussion

There are no quick solutions to the complex problems in the health sector in developing countries. Among others, e-health has been identified as one possible solution to address some of these problems. Under right circumstances new technologies can improve the quality of care and efficiency of services. Governments as well as private sector around the world have become aware of the potential of new technology. But the enthusiasm of policy makers and investments in infrastructure only cannot enable e-health to enhance health services. The expansion of knowledge and skills in e-health at grass-roots level (among health professionals) and their acceptance of these techniques are imperative factors for e-health to become sustainable.

Our survey revealed that although the majority of students were familiar with the term e-health their knowledge and skill to practice this modality was extremely limited. Indeed, the limited access to computers and the Internet is a serious barrier in developing countries. Unlike in industrialised countries, computers are still a luxury in the developing world. Presumably this barrier has limited the advantages they may gain from new technologies. This limitation also represents a significant factor preventing them from acquiring necessary knowledge and skills in e-health. The so called 'digital divide' is still a formidable barrier to be overcome [16].

Despite the fact that students have limited access to computers and the Internet, the majority of them are computer literate. In fact, there is a growing interest in computers and the Internet in the developing world [12]. The students found that one of the main barriers for them to develop appropriate knowledge and skills in e-health was the absence of formalised e-health educational components in the medical curriculum. There is a need to provide knowledge about the fundamentals of e-health, basic concepts and various applications with particular emphasis on low-cost e-health modalities. Such education must also include a practical component to provide medical students with necessary hands-on skills. This preparation would enable students to choose relevant applications in their own practice suitable for their own circumstances.

Conclusions

Health systems in developing countries can be a potential beneficiary of e-health applications. Not only local governments, but also the international organisations such as the UN and the WHO have identified the potential of ICT to address the health needs of developing countries. Efforts have been made to promote e-health in developing countries by investing funds, initiating projects and introducing technology and improving infrastructure.

However, in this effort, e-health education has been the least attended area. The knowledge, acceptance and enthusiasm of local health professionals, particularly doctors are vital if e-health is to be a significant component of mainstream healthcare. Cultivation of a positive attitude towards e-health requires systematic education. Students must be provided with a formalised e-health education within their medial and health curriculum to establish knowledge in basic concepts, terminology, various e-health applications, successes and failures in current practice. Such education must also include a practical component to provide hands-on skills.

Undoubtedly the impact of digital divide is still a serious problem for developing countries. Concerted efforts must

be made to enhance the access to technology in these countries. The potential of low-cost e-health applications in developing countries is still untapped. In order to use low-cost e-health modalities to their full capacity one must have an appropriate knowledge in e-health and understanding of local needs. Formalised e-health education embedded into medical and health curriculum is needed to enhance the knowledge and skills of local health professionals.

Acknowledgments

We thank the University of Queensland (New Staff Start-Up Research Fund) for funding this research. We also thank the medical students of Sri Jayewardenepura University for their participation in the study.

Importance of Public Health Informatics: A Survey of Public Health Schools and Graduate Programs in the United States

Janise Richards, MS, MPH, PhD

*Centers for Disease Control and Prevention, Atlanta Georgia, USA**

Abstract

This paper examines the importance of data, information, and informatics to public health practice. Forty public health academicians from 40 schools and graduate programs of public health were interviewed. All agreed that informatics was important to public health practice. A qualitative analysis of their comments revealed their beliefs on the importance of informatics skills and knowledge to the practice of public health. The resulting comment groups varied from "some skills are more important than others" to "need all the skills." Eight "importance" comment groups were formed: 1) skills for all professionals; 2) some skills more than others; 3) yes, they need all the skills; 4) skills to become better practitioners; 5) usefulness to practitioners; 6) communication with public; 7) they're [the public] are depending on us; and 8) the future

***Keywords*:**

public health; informatics training; workforce development; needs assessment; education

Introduction

Unlike medical informatics, public health informatics is not a well established field. [1] Because medical informatics developed into a field first, much of the literature in American journals regarding informatics reflects the 'medical model.' There is little literature that reflects the 'public health model.'[2] Often medicine and public health are thought of as interrelated.

Medical professionals think of public health as a subspecialty of medicines and public health professionals view medicine as an arm of public health. [3] Each point of view has merit. Since managed care has encouraged clinicians to emphasize prevention and to examine the use of population-based outreach services, the differences between the two are becoming less evident. However, the two have different primary foci; the patient for medicine, and the community for public health. Also the role of information, core functions, data and information sources are more wide-ranging in public health practice. [1,2,3,4]

The role of information in public health

The foundation of public health is information. The 1996 World Health Report cites the continuing need to "disseminate health information widely, in the shape of epidemiological and statistical data, reports, guidelines, training modules and periodicals." [5] In practice, all the core public health disciplines – epidemiology, biostatistics, behavioral sciences, environmental health, and policy and administration – are supported by information and information technologies. Furthermore, according to the Institute of Medicine (IOM) the substance of public health is organized community efforts aimed the prevention of disease and promotion of health. It links many diverse disciplines and rests upon the scientific core of epidemiology. [2] Since epidemiology depends on the effective collection, analysis, interpretation, and dissemination of information, information is the foundation of public health.

Core functions of public health

In the IOM model, three core functions are necessary for sound public health practice: assessment, policy development, and assurance. A fourth core function, continuous evaluation, links the three core functions. [2] Each of these core functions is data and information driven.

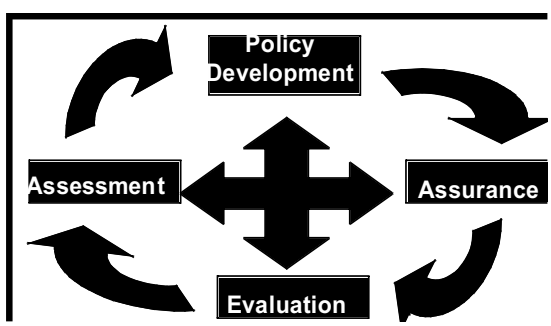

Figure 1 – Core Functions of Public Health

Assessment depends primarily on the core public health disciplines of epidemiology and biostatistics. [4] It consists of activities such as: surveillance; identifying needs; analyzing problems; collecting and interpreting data; case-finding; monitoring and forecasting trends; research and developing outcome indicators.

Policy development is a process by which public health professionals formulate, advocate and implement the appropriate action determined from the assessment of the situation. Policy development includes: decision-making;

mediating opposing views; negotiating common goals; developing programmatic goals and objectives; and allocating and mobilizing resources.

Assurance is the process that examines the quality of the situation, or impact of the policy or program implemented. Assurance activities include: determining the necessary services are provided to meet stated goals; regulating services and products; maintaining accountability and progress reports; and testing outcome indicators.

Evaluation is the ongoing assessment of the activities and processes. Evaluation data are gathered through a wide variety of sources.

Public health data sources

The public health core functions are performed in a data and information enriched environment. Data are collected through methods such as surveillance, surveys, and clinical assessments. The types of data generated include: demographic; mortality; morbidity; laboratory; physical assessments; health resources; health resource utilization; natality; disease occurrence; environmental assessments; and, public opinion data. There are as many sources for public health data as there are situations for assessment.

Public health information sources

Public health information sources also are unlimited. [6] Two common sources of categorized, meaningful data are Vital and Health Statistics and the National Health Interview Survey. Other more complete information sources include: the Morbidity and Mortality Weekly Report (MMWR); health department reports; health professions journals; newspapers; and magazines. Informal public health information sources such as phone calls, faxes, email, or meeting notes are a rich source of data and information about individuals and groups dealing with a specific public health situation.

Importance of public health information sources

Even with all the data and information sources available, public health professionals have difficulties obtaining the data and information they need. [5] Public health data and information sources lack standardization in organization, nomenclature and electronic transmission. Of the data are fragmented due to redundant collection or episodic data collection. Most notably, data and information is not always up-to-date. Timeliness of data is of importance. Nearly all public health actions depend on what is presently occurring in regards to a particular public health problem in a community.

If public health as a field is to become more effective, public health professionals need timely, quality information, better ways to communicate data and information, and betters tools to analyze new information. [1] Innovative methods of storing, organizing and disseminating the millions of pieces of data gathered during the core functions of public health need to be researched and tested. [6]

Because information is the major component of public health, and there is a need for public health professionals to know how to access, analyze and disseminate data and information. This study was designed to examine public health academician's belief in the importance of informatics for public health practitioners and the need to have informatics training in schools and graduate programs of public health.

Methods

This descriptive, qualitative study included 28 accredited schools of public health, 11 graduate programs in community health and 20 graduate programs in community health/preventive medicine which offer a MSPH or MPH degree within the United States.

A letter was sent to each school and program describing the study. A follow-up telephone call reached academicians at 21 public health schools, 14 graduate programs in community health/preventive medicine and 5 graduate programs in community health for a total population of 40 public health academicians. During this contact, one-on-one telephone interviews were scheduled.

Data were analyzed from the interview surveys. The qualitative data analysis was conducted using a note-based analysis and open coding technique. [Note-based analysis involves immediately summarizing the notes take during the interview. Open coding describes the process of breaking down, examining, conceptualizing and categorizing the data.] Categories are the classification of concepts based on the comparison of one concept against another and those that appear to have similar characteristics are grouped together. [7]

Results

When asked "do you believe that informatics or informatics-related competencies are important for public health practitioners?" – 100% of the contacts said yes; several were emphatic. When asked why they believed informatics was important a variety of reasons emerged. Analysis of the comments revealed some interesting groupings.

Skills for all professionals

One subgroup of comments indicated these skills are necessary for any person to function in a professional capacity. This *skills for all professionals* subgroup had a global view of the need for informatics. The terms "computer age" and 'computerized society" were used to describe their belief; as one contact stated: "…you can't get along in the real world without these skills today."

Some skills more than others

Another subgroup of comments stated that some skills in informatics are needed by public health practitioners, but not all. This *some skills more than others* subgroup believe database use and development skills, information access skills, data and information analysis skills and an understanding of how communication technologies work is what should be taught. As one member of this subgroup succinctly stated: "…but not every practitioner needs to know all the details."

Yes, they do need all the skills

On the opposite end of the spectrum, the *yes, they do need all the skills* subgroup believes "there is a clear need to have expertise in informatics and the students need to understand the issues as well as the skills and knowledge." They believe the "shift to online based information is here to stay and [they] don't see any way to function in the public health arena without access to information technology sources." To teach these skills 'far outweigh the costs of the training and we need to support and train public health practitioners in this area."

However, "technology has gotten sophisticated so very quickly and those teaching need to understand the whole field of informatics and what it has to offer to public health. The faculty see only a narrow bit that is in their specialty area." In looking towards the future, they believe "we're not really preparing our public health students for the future" and "we think that it is criminal to graduate students without these skills."

Skills to become better practitioners

This subgroup believes informatics provides the tools to move the field of public health forward and there is a need for informatics *skills to become better practitioners*. They foresee that knowing when to use the "appropriate tools in each situation" will allow practitioners to be "more effective and cost-effective" in the practice of public health. Because this increased ability to be more effective, "informatics needs to become a basic professional skill." One person stated: "There is a clear need within public health to be able to use information technology."

Usefulness to practitioners

In this subgroup informatics *usefulness to public health practitioners* comments were categorized into different types: *information access*, *remote access,* and *cost-effectiveness*.

Widespread understanding of technology and information management concepts will "improve information access by practitioners" and allow practitioners to collaborate to "provide better services in their state or region." As one contact commented: "there is a lot of information to access and to be able to provide information in an intelligent way for others to find and use in practice, is a valuable need for public health."

Remote access was commented upon within this subgroup. In rural areas public health practitioners have limited access to information sources. The contacts believe information technology would greatly improve the practice of public health in these regions.

The cost effectiveness concept was stated by contacts in there belief that information technology has the ability to provide, "the latest developments in public health and has a lower cost and an easier accessibility than paper."

Communication with public

Another subgroup of comments characterizes the importance of informatics and information technology, the Web in particular, as methods to improve communication with the public. They believe it is "a vehicle by which we can communicate with the general public and with each other." They see expertise with information technologies necessary for public health practitioners to be able to "disseminate public health related information to the community and practitioners who want to implement intervention and prevention programs." A caveat to this improved communication is the frustration caused by lack of hardware in some populations and "there is a potential for creating a technology elite."

They're depending on us

An extension of the *communication with public* subgroup believes public health practitioners should take a leadership role in placing accurate health information on the web. The *they're depending on us* subgroup believes: "the world expects to find health information on the web"; the world expects that the health information on the Internet to be accurate"; and "public health has an obligation to provide accurate information [on the web]."

Future changes in practice

This subgroup believes the *future changes in practice* and information technology are inseparable. They believe graduates from schools and programs in public health "won't be employed in traditional public health programs, but in managed care organizations and the technology will become increasingly important in that arena," and "with managed care, from my occupational medicine point of view, data management is becoming more and more important to primary care." They also stated: "public health is moving away from the clinical services toward

the core areas of public health and within the core areas information is essential. For example, we need to maintain and access immunization registries to be able to accurately monitor health and well being of children and have the people with the skills to maintain them," and "in public health state departments [we're] moving from the delivery of services to the evaluation of programs which will emphasize the need for them [public health workforce] to have informatics skills and knowledge.´ This subgroups was very ardent in their beliefs. One contact summed up the thoughts persuasively by stating: *this is not a trend, but a modus operandi for the future*.

Conclusions

All forty contacts, regardless of their academic affiliation, stated they believed informatics and informatics related concepts were important to the practice of public health. They understand the importance of timely, accurate, and quality information. Yet, they seem to believe the information will automatically appear into information systems. To have the quality of data and information needed to practice public health effectively, the data must be gathered and organized in a standardized manner, and made available in an easily accessible form within information systems. The ability for public health practitioners to develop systems to ensure accessible, quality information should be provided through public health informatics training.

The emphasis on the information component is important, but there is value in understanding the technology. The distinct advantage of training in public health informatics is: The practitioner would not only have knowledge of what the data was needed for; they would be able to determine what technologies would be best suited to deliver the data and information expediently in the most useful format; and they would have the skills and knowledge to best organize the data or information to facilitate communication to other public health practitioners.

There is a need to develop information systems and technology to improve public health practice. Schools and graduate programs of public health are slowly developing courses in public health informatics to meet this need. [8] They believe informatics is important to the future of public health.

Abstract

As more health information technologies become part of the health care environment, the need for physicians with medical informatics competencies is growing. In 2006, a survey was created to determine the degree to which the Association of American Medical College's Medical School Objectives Project (MSOP) medical informatics competencies had been incorporated into medical school curricula in the United States. Methods: a web-based tool was used to create the survey; medical education deans or their designees were requested to complete the survey. Analysis focused on the clinician, researcher, and manager roles of physicians. Results: Seventy usable surveys were returned. Many of the objectives were stated in the schools' respective curricula and the competencies were being evaluated. However, only a few schools taught and assessed the medical informatics objectives that required interaction with health information. Conclusion: To insure that physicians have the knowledge, skills, and attitudes to effectively and efficiently interact with today's health information technologies, more medical informatics concepts need to be included and assessed in all undergraduate medical education curricula in the United States.

Keywords:

education, medical, undergraduate; medical informatics; hospital information systems; decision support systems, clinical

Introduction

Within the next decade, a large majority of hospitals and health care centers in developed nations and many in developing nations will have electronic health records and other forms of health information technology. Physicians will be expected to use these tools to improve patient safety, enhance the quality of care, and reduce costs. This expectation requires that physicians be trained, not as medical informaticians but as knowledgeable users of the health technology tools. However, most education in medical or health informatics has focused on the knowledge and skills needed by informaticians rather than health care professionals.

Recently in the United States, the President authorized the creation of the first Office of the National Coordinator for Health Information Technology. Several legislative initiatives were undertaken to promote the use of information technology within healthcare to improve process, quality and safety, thereby improving the health of our citizens. The promise of widespread adoption of electronic health records with the concomitant capabilities of provider order entry, decision support, and data mining for clinical research, as well as quality and safety evaluations, is about to become a reality. However, significant questions exist as to whether or not physicians will have the competencies necessary to effectively use these systems to achieve the goals outlined by the President and legislature.

Europe and Canada have long been leaders in the training of informatics-facile health care providers. The work of the European Centre for Medical Informatics, Statistics and Epidemiology (EuroMISE) has provided an early framework for such education in Europe.[1] The International Partnership for Health Informatics Education is in part an outgrowth of the earlier efforts and, in an environment of increasing globalization, emphasizes the need for international components in informatics education.[2]

Canada was also an early leader in medical informatics education and took a different but equally effective approach by integrating applied medical informatics into the undergraduate medical curricula.[3] However, such education must evolve with the changing technologies and the demand for more and more health care professionals to become information literate has resulted in an evaluation of current practices with more emphasis being given to emerging trends in both informatics and health.[4]

Other nations are beginning to recognize the need for more informatics training in the health professions.[5-7] In an attempt to address these very real issues, the International Medical Informatics Association developed recommendations on education in health and medical informatics.[8] These recommendations are the initial step in developing the educational framework necessary to insure that students possess appropriate qualifications to work in an information technology intensive health care environment.[9]

Leaders in medical informatics in these countries and others are calling for more targeted educational programs to insure that the systems being implemented will have physicians trained to use them.[10] However, the integration of such training into health professions curricula has been difficult at best and quite slow to develop.

Need for such training was beginning to be recognized in the United States in the 1980s with several calls from major organizations to prepare physicians for a future in an automated health care environment by integrating the necessary skills into the educational process.[11-13] However, little was realized in the form of concrete programs from these early inducements.

Understanding the potential impact of the growing interest in health information technology on the practice of medicine, and trying to take a more proactive stance in insuring that undergraduate medical students had a firm grounding in the knowledge, skills and attitudes necessary to become technologically savvy health care providers of the future, the Association of American Medical Colleges in 1998 convened an expert panel to develop educational objectives to satisfy this goal. The medical informatics panel of the Medical School Objectives Project (MSOP) II identified five medical informatics relevant roles played by physicians – lifelong learner, clinician, educator-communicator, researcher, and manager. The recommendations for educational content were developed within this framework and published in 1999.[14]

In part because of the increasing interest on the part of the government in facilitating widespread adoption of health information technology, in part because of the dearth of articles published about new educational programs in medical informatics in undergraduate medical curricula, and in part because of a growing need for information literate physicians, a small group of the educational leadership within the Group on Information Resources of the Association of American Medical Colleges surveyed and analyzed the responses of the 127 United States medical schools to determine whether or not they had implemented the MSOP medical informatics educational objectives and, if so, to what extent were the implemented.

Methods

An initial request to participate in the survey was sent to the respective deans of medical education at the 143 discrete medical schools in the United States and Canada. The deans were asked to either respond to the survey or refer it to someone who was knowledgeable about medical informatics content in the curriculum. The Web-based survey asked participants to respond to questions formulated directly from the MSOP II medical informatics educational objectives. These questions were grouped by the physician role with sub-groupings around concepts.

An initial question addressed whether or not the respondent was familiar with the MSOP Medical Informatics educational objectives. The subsequent questions asked the respondent whether or not each of the objective concepts was taught, had stated objectives, and was assessed. At the end of each of the five role divisions the respondent was asked to indicate who taught the concepts and how the concepts were assessed.

While virtually all of the respondents indicated they were familiar with the MSOP medical informatics educational objectives, the responses differed widely in regards to teaching, stated objectives, and assessment. In following up with a number of the participants about responses, it became apparent that many thought the medical informatics content was being taught as an integrated component of the clinical years. However others from the same institutions, many with long standing clinical information systems, stated that their medical students were exposed to these systems but did not have formal training or experiential learning with these systems.

Because of these discrepancies, a second survey was developed that limited responses to stated objectives and assessment because of the belief that having a stated objective would result in some educational action and would eliminate the possibility of someone assuming rather than knowing that the concepts were being taught.

The request to participate in the survey was again sent to the deans of medical education unless there was a different respondent on the first survey. The second survey was also Web-based and a request for participation was made in early 2006, almost a year after the first survey. Interestingly, individual school responses showed little change, however, several additional schools indicated establishing objectives.

Because the attributes for being facile with health information technology in the today's health care environment focused on three of the five physician roles, the responses for Life-long Learner and Educator-Communicator were not considered for this study. In addition, while data was collected on Canadian medical schools, because of their early embracing of the need to teach medical informatics in undergraduate medical education, only the responses from United States Medical Schools have been evaluated.

Results

Seventy usable surveys were "virtually" returned. Ninety-six percent of the respondents were familiar with the MSOP medical informatics educational objectives and eighty-eight percent indicated that there had been an overall strategy to integrate medical informatics objectives into the curriculum. However, the results of the specific competencies did not support this.

Clinician

Within the sub-group of effective use of clinical information systems, 60% of the respondents indicated that they had a stated objective on retrieving patient-specific information from a clinical information system and 49% assessed the competency. Forty-four percent had a stated objective on displaying selected subsets of information available about a given patient and 36% assess the competency. Forty-six percent had a stated objective about recording specific findings about a patient in a clinical

information system while 47% assessed the competency. Forty-six percent had a stated objective on recording orders (CPOE) directing the further care of the patient and 36% assessed the competency.

The sub-group of interpreting laboratory tests scored higher. Seventy percent of the respondents had a stated objective about recognizing the knowledge limitations of standard laboratory measurements and 66% assessed the competency. Seventy-seven percent had a stated objective about demonstrating the ability to integrate clinical and laboratory findings while 86% assessed the competency.

Within the sub-group of incorporating uncertainty explicitly into clinical decision making, fifty-seven percent of the respondents had a stated objective on demonstrating the ability to quantify and communicate the degree of certainty associated with specific items of scientific and clinical information and 50% assessed the competency. Forty-six percent had a stated competency on demonstrating the ability to identify and locate when possible the crucial pieces of missing clinical information and determine when it is appropriate to act on incomplete information and 40% assessed the competency. Sixty-three percent had a stated objective on demonstrating the ability to integrate verbal and statistical sources of medical knowledge with the facts of a specific clinical case and 61% assessed the competency.

Within the critical use of decision support tools sub-group, sixty-nine percent of the respondents had a stated objective on using textbooks and journal articles and 67% assessed the competency. Thirty percent had a stated objective on using diagnostic expert systems and fourteen percent assessed the competency. Twenty-three percent had a stated objective on using advisories or alerts issued from a computer based records and fourteen percent assessed the competency.

In responding to a student's ability to formulate a treatment plan, fifty-seven percent of the respondents had a stated objective that students should demonstrate the ability to express the relative certainties of a differential diagnosis while 69% assessed the competency. Sixty-one percent had a stated objective on expressing the relative risks and benefits of outcomes and treatment options while 66% assessed the competency. Forty-six percent had a stated objective on taking action by balancing risks and benefits while 53% assessed the competency.

Within the sub-group of respecting patient (and physician) confidentiality, 76% of the respondents had a stated objective on demonstrating the knowledge of the legal, ethical and medical issues surrounding patient documentation including confidentiality and data security while 79% assess the competency. Thirty-three percent had a stated objective on demonstrating the ability to use security-directed features of an information system while 27% assessed the competency.

Researcher

The first of the researcher group deals specifically with the use of clinical information systems. Twenty-four percent of the respondents had a stated objective on determining a practice's case mix and 20% assessed the competency. Twenty-nine percent had a stated objective on determining the incidences of diagnoses in a practice and 26% assessed the competency. Forty percent had a stated objective on testing the efficacy of a new treatment and 33% assessed the competency. Fifty-six percent had a stated objective on formulating testable hypotheses and 50% assessed the competency. Fifty-one percent had a stated objective on collecting, organizing, and interpreting data while 53% assessed the competencies.

Within the sub-group about determining what data exist relative to a clinical question or formal hypothesis, seventy-one percent of the respondents had a stated objective for demonstrating the ability to use information technology to locate existing data sources and 60% assessed the competency. Thirty-three percent had a stated object for demonstrating knowledge of data sources (including medical records claims and reimbursement information and online data) at one's own institution by identifying how these might be used to address a specific clinical question posed as research and 20% assessed the competency. Thirty-one percent of the respondents had a stated objective for demonstrating the ability to identify and locate existing data sets no maintained at one's own institution (e.g., national registry data) that might be used to address a specific clinical question posed as research and 16% assessed the competency.

For the sub-group executing a plan for data collection and organizing data for analysis, 24% of the respondents had a stated objective for selecting and appropriate computer database tool for collecting and organizing data and fourteen percent assessed the competency. Twenty-nine percent had a stated objective for properly representing data from a study in a form that is useful and supports computer-based analysis and sixteen percent assessed the competency.

Within the sub-group of analyzing, interpreting, and reporting findings, 23% of the respondents had a stated objective for selecting the appropriate computer software tools for analysis of data and ten percent assessed the competency. Thirty-one percent had a stated objective for using software to perform simple statistical analysis and portraying the results graphically and 23% assessed the competencies. Thirty-one percent had a stated objective for interpreting the reports of statistical software analysis and 27% assessed the competency.

Manager

There are three sub-groups within the Manager grouping. The first of these is the appreciation of the role of information technology in relation to managing the cost of medical care and its impact on individuals and society. Twenty-three percent of the respondents had a stated objective on using on-line sources of health care financing information and eleven percent assessed the competency. Thirty-nine percent had a stated objective on continuous quality improvement and process management and twenty percent assessed the competency. Twenty-four percent had a stated

objective on how information technology can be used to develop, implement and monitor compliance with clinical pathways and other forms of patient care protocols and eleven percent assessed the competencies. Thirty-three percent had a stated objective on how clinical information in the aggregated can be used to determine health care services planning for populations and 23% assessed the competency.

Within the sub-group of formulating and making decisions for individuals and groups, 55% of the respondents had a stated objective on demonstrating knowledge of cost/benefit issues in health care and 29% assessed the competency. Fourteen percent had a stated objective on using a decision-analysis package and seven percent assessed the competency. Thirteen percent had a stated objective on using software utilities assessing patients and six percent assessed the competency. Thirty-nine percent had a stated objective on incorporating economic and cost perspectives into decision making and 23% assessed the competency.

The last sub-group dealt with working effectively as an individual in inter-professional groups and as a member of a complex health care system. Nineteen percent of the respondents had a stated objective on using electronic personal and clinical scheduling systems and nine percent assessed the competency. Twenty-one percent had a stated objective on archiving and organizing digital information of personal and clinical import and fourteen percent assessed the competencies. Twenty-four percent had a stated objective on demonstrating knowledge of online resources for legislation, political advocacy, and local health care policy setting and six percent assessed the competency.

General questions

In all three of the physician role groupings, the content was taught generally through embedding it in core course. A few schools had an elective course in medical informatics and fewer still had a core course in medical informatics. Because the primary mode of teaching was through integration with other content, almost all of the assessment of competencies was done as part of a general educational evaluation schema. However, several schools had tests specific to medical informatics or used these in conjunction with the general assessment methodologies.

Discussion

The medical informatics educational objections presented by the MSOP expert panel were developed around the concept of information discovery and not predicated on computer literacy. For this reason, a number of the competencies can be taught without use of a computer. Examples of this are found in the interpretation of laboratory tests and the ability to formulate a treatment plan.

There were a total of 41 questions in the clinician, researcher, and manager role groups. Of those, 27 required interaction with a clinical information system or some ancillary system containing patient information. Eleven questions involved educational objectives that could be met without such interaction. Three questions related specifically to the competencies within the life-long learner role group but were also closely linked to clinician and researcher information management.

Of the five roles, the greatest number of medical school having stated objectives and competency assessments was found in the life-long learner role. This corresponds to the increase in teaching evidence-based medicine and the greater involvement of libraries for development of knowledge-based searching capabilities. For this reason, the life-long learning correlates, although requiring the use of computers to find information, were grouped separately.

In analyzing the responses by question type, less than a third (30.7%) of the medical school respondents had stated objectives for the 27 questions requiring use of computer systems and only slightly more than a fifth (21.1%) assessed competencies. There was one exception. Sixty percent of the respondents did have a stated objective about retrieval of patient-specific data from a clinical information system and 49% assessed the competency.

Of the three life-long learner correlated questions, approximately two thirds (67.7%) of the medical school respondents had stated objectives and slightly less (62.7%) assessed the competencies. Of those questions that did not require interaction with a computer system, over half (58.6% and 56.7% respectively) of the medical school respondents had both stated objectives and assessment of competencies.

In looking at the raw data and comparing the assessment to the stated objectives in all three of the physician role groups, there were 28 instances in which competencies were assessed within seven sub-groups without having stated objectives. These were virtually all in the clinician role and fell primarily under the non-computer based questions. A possible explanation is that the concept might have been considered too granular to include as a stated objective while it was included as part of a clinical evaluation schema.

Conclusion

Seventy of 127 surveys assessing the degree to which the MSOP medical informatics educational objectives have been incorporated into undergraduate medical curricula in the United Stated were completed. An analysis of these found that while many of the medical informatics concepts relevant to the clinician, research and manager roles were being addressed in the curricula, when broken down by those concepts that required health information technology interaction, only a few schools had stated objectives and fewer assessed the competencies.

The survey respondents were self-selected, and anecdotal information suggests that many who did not complete the surveys chose not to do so because they had little or no medical informatics in their curricula. Also, while these objectives are valid today, as HIT systems evolve and become more integrated into the health care system, the objectives also need to evolve. Some progress has been

made but much more needs to be accomplished to insure that physicians will be able to efficiently and effectively use the health information technology being installed in hospitals and health centers.

Establishing A National Resource: A Health Informatics Collection To Maintain The Legacy of Health Informatics Development

Beverley Ellis[a], Jean Roberts[a], Helen Cooper[b]

[a] *Health InformaticsU nit, Lancashire School of Health and Post-Graduate Medicine, UCLAN, Preston UK*
[b] *Health Team, Library and Learning Resource Service, University of Central Lancashire, UK*

Abstract

This case study report of the establishment of a national repository of multi-media materials describes the creation process, the challenges faced in putting it into operation and the opportunities for the future. The initial resource has been incorporated under standard library and knowledge management practices. A collaborative action research method was used with active experts in the domain to determine the requirements and priorities for further development. The National Health Informatics Collection (NatHIC) is now accessible and the further issues are being addressed by inclusion in future University and NHS strategic plans. Ultimately the Collection will link with other facilities that contribute to the description and maintenance of effective informatics in support of health globally. The issues raised about the National Health Informatics Collection as established in the UK have resonance with the challenges of capturing the overall historic development of an emerging discipline in any country.

Keywords:

health Informatics, legacy, knowledge management, access

Introduction

Existing, lost and retained multi-media materials relating to topics in informatics to support health care represent a challenge in the context of the complexity of the current Health Informatics (HI) landscape. Absence of materials is most frequently felt by students and researchers, although the HI reference content also directly frames current operational developments. Looking at past projects and processes, and their longevity, success and failure may give pragmatic indicators for the level of acceptance or reluctance to embrace current development. If literature generated in the initial, basic and developmental phases of the projects are still available for reference, it will be possible to identify milestones and situations that can explain current entrenched positions and perhaps suggest catalysts to success that were missed on the first iteration.

The closure of the NHS in England Information Authority and the realignment of its roles and responsibilities, predominantly under the NHS Connecting for Health (NHSCFH) agency National Programme for IT (NPfIT) [1], made its reference resource library surplus to requirements. Members of the Health Informatics Unit at the University of Central Lancashire School of Health and Post-graduate Medicine (UCLAN) [2] had, with other academic colleagues, been considering how to sustain the legacy of HI. UCLAN was successful in bidding to house the residual resource; this is mainly due to its track record in managing and making available other specialist collections, such as the Livesey Collection relating to the Temperance Movement in the early 1800s, and the media collection of the Sport England organisation.

The National Health Informatics Collection (NatHIC) entity has been launched as a Collection rather than an Archive in order to confirm the commitment to maintain the heritage as a living and growing source. Personal donors who are, or were, key players in the domain have added to the initial materials, and continue to do so.

In order to keep a live Collection, the NatHIC objectives encompass making links to valuable knowledge facilities established elsewhere and to bodies who make available organisational resources on a rapidly changing basis. The linkages are in addition to managing physical resources on-site at UCLAN. The Collection is being made available for the benefit of all interested parties, not just those with close links to our university. NatHIC is intended to be available by reference, and where possible, loan of its content. NatHIC aims to act as a hub, maintaining physical multi-media resources, signposting other collections and materials, making linkages with other facilities and providers and providing guidance on identifying sources to those interested in informatics to support the health care domain. Users will not just be within the NHS but will also be from other care delivery agencies, their (commercial) solutions and service providers, and academia in all of the home countries and beyond. The desirable content will span both the historical legacy of HI and its contemporaneous / future materials, from a UK and wider perspective.

Method of development

The initial establishment of a repository of materials relating to the development of health informatics across the UK was first considered in the 1990s by members of CHIRAD,

Selected for best paper award.

a research institute in Winchester [4] whose members had had long and active participation in both teaching and learning and in the development of domain through the British Computer Society professional learned society and its subsidiary body, now called the Health Informatics Forum [5]. Despite various funding proposals the resources were not at that time available. However, the situation had changed sufficiently that in 2006 when substantial materials for the Collection became available, it was possible to put ideas into action at UCLAN. This Case Report paper describes the current situation, and discusses issues for future development in terms of content and accessibility for the domain internationally.

Access

Logistically, all users need to be recognized as authorized to use the Collection if they wish to loan any content. They must initially be registered as Distance (Associate Staff) Users of the UCLAN Library. This is a process already deployed in order to facilitate and enable generic library access by local NHS employees in the North West of England. It requires only completion of a form and provision of a photographic image to be used as authorisation if the holder ever wishes to physically enter the library on campus. UCLAN strives for equity of access for all through being cognisant of disability equity criteria including SENDA [6] Disability legislation.

NatHIC is initially intended to encompass any materials that impacts upon the HI developments across all the four UK home countries. Its principles and the lessons learnt from its establishment will perhaps be of use to other countries starting to identify similar omissions in their HI history. It is hoped that NatHIC will eventually interface to other resources elsewhere giving a global picture of HI developments over time.

Limitations

The current processing of donated will only capture legacy material that will set health informatics developments into context. UCLAN are putting into place mechanisms to include new works donated by publishers, authors and organisations creating informative resources over time.

Commentators have questioned the value of a back catalog rather than solely a comprehensive, contemporaneous resource. There are many significant instances where prior work has a distinct impact on current thinking. One particular instantiation of the continuing relevance of past concepts is a data quality principle of the early 1980s, where healthcare practitioners lead by the late Dame Edith Korner stated that a healthcare organisation should only (be required to) collect that information 'without which it is not feasible to be deemed to manage effectively' [7]. Thus data had to be collected at source, where any errors would be more readily identified and corrected; and that data had to be owned and have a purpose at that level in order to ensure the highest quality was maintained. At the time (1983) this reduced the number of resource wasting ad hoc studies that were previously carried out to answer one-off queries from government and strategic bodies. That principle can be seen reflected in the NPfIT 'Do once and Share' initiative but many younger HI professionals do not grasp that the underlying principles was defined over 25 years ago!

Others suggested that the current classification of cited publications was sufficient to afford a useful view of HI over time. However, as Machan [8] identified at the MIE2006 congress in Maastricht , analysis of the cited literature has a considerable omission in its knowledge capital – that of the negative findings and problem issues that are not formally published, but may have come to light in 'grey literature', trade papers and transient materials, such as newspapers, blogs and electronic commentaries.

As the Collection enlarges, there is a risk that space will become a premium. At that time, a usage review may be necessary to refine the most frequently requested sources to a particular geographic, technological, health or time focus, yet to be identified. Current library issue tracking systems can contribute to profiling what materials can/should be culled and can inform debate about what criteria should be used for content management.

Decisions relating to the scope, content, eligibility of materials for the Collection cannot be left to knowledge managers, library professionals or a domain experts with a close personal interest, (for example-ourselves) in maintaining the Collection, so an Editorial Management Committee with a range of areas of expertise is being established to reflect the extensive inclusive nature of the HI domain.

Determining ongoing functionality

Immediately after the launch of the Collection, a collaborative action research methodology was deployed in a Master Class facilitated by the NHS HI Faculty [9]. The session reflected on the basic Collection and its functionality and identified areas for further enhancement. These suggestions will be addressed over time in order to achieve as high quality resource as is feasible, given current technologies, funding and resources. The findings from the session were subsequently written up and validated through wider dissemination and feedback through the Faculty web area.

Various questions were identified, relating to establishing and maintaining resources for the benefit of all interested parties, they are explored further in this paper.

- What are the core resources that should be preserved
- What is the longevity of formal publications in practice
- How is it best to make available access to historic and future materials relating to HI
- Can a mechanism be developed that will accommodate self-input to the repository and yet avoid 'vanity' publication
- What target materials should be included in (or accessible through) the remit of NatHIC

Why is a comprehensive resource necessary

Health Informatics is still an emerging discipline, even after over thirty years [10] and as such is frequently seen as

an operational adjunct and a fragmented research domain. There is evidence that students, researchers and commentators on HI developments over time had difficulty finding historic materials to:

- set the context for current work
- explain the strategic direction of HI over time
- provide details of major national and local HI initiatives that were completed or had refocused for subsequent phases

In addition, there was anecdotal evidence, strongly articulated by professionals in the field that current initiatives were, or were likely to, repeat the mistakes and not able to avoid pitfalls that had been negotiated previously [11] if they did not take into account the way such challenges were addressed in the past.

Core content

It is not logical for NatHIC to deploy scarce resources to replicate / duplicate established sources of relevant material unless they are thought to be at risk. NatHIC is in the process of exploring links and collaborative working with repositories such as US National Library of Medicine, UK National Library of Health, and Department of Health with a view to providing secure gateways to their resources from NatHIC.

In order to be readily accessible and searchable, NatHIC will require ('a smart') classification and categorisation of its content. In view of the eclectic nature and wide range of that content, which cuts across traditional library resources, further work is ongoing exploring the suitability of existing ontologies and classifications.

Currently, the inclusion of materials is organic, decisions being based predominantly on advice about the seminal nature of thematic materials; but in due course a strategic acquisition plan for materials that the community / peer group see as important will be necessary.

The materials, nature and the links to NatHIC confound current definitions so the current structured strategies to facilitate effective searching are incomplete. For example – promotional literature aimed at a lay audience that is currently used to explain a proffered guarantee relating to care records handling will no doubt be varied because of current concerns [12]. It will be necessary to retain copies of the original documents to contextualise the emotions surrounding 'opting in or opting out' of the formal shared records plans for the 'National Spine' [1].

It was suggested that NatHIC also explored the management and retention of Case Study reports describing both completed assignments and projects still in progress in addition to issues papers created by various sources over time. There are a number of active groups in the field already cataloging such information, however these are disparate and diffuse, predominantly managing only the status reports of projects they themselves funded or support (for example Department of Health Service Delivery and Organisation R&D Programme : www.sdo.lshtm.ac.uk/commissioned projects.htm or the European Commission Europa site : europa.eu). NatHIC therefore could bring together linkages to those sources to produce a full picture of research activity across the country, and by UK participants wherever the project is lead from.

Also felt to be useful for ad hoc reference and download were templates and schemas that previously were only made available with specific initiatives and not available at other times, including business case presentations, project initiation documents and audit schemas.

Format

The permissible media for submission of items for the Collection were felt to be less crucial than the content. However it was recognised that some media were made obsolete by changing technologies. It is the intention of UCLAN, over time, to explore the development of mechanisms to make best efforts to keep seminal material readily accessible. For example – degraded old documents can be made available in scanned electronic form; obsolete e-media can be re-versioned forward as required (such as VHS video formats being transferred to CD-ROM). The experiences of other locations, such as the British Library will be sought to frame this activity.

NatHIC 'material content' will consist of physical hard copy media, audio and video/CD-ROM in so far as are still operational, robust electronic documents where they are provided by a source organisation (and subsequently where necessary to preserve content from obsolescence) and also links to other repositories, sources of content.

Where possible, donors will be encouraged to provide electronic media and direct access to back catalogues.

It was identified that users of NatHIC may only have a requirement for selected materials from within a journal / report and that partial download facilities should be available wherever possible. This will require a level of pre-processing which is not yet in place.

Moderation

As stated previously, NatHIC is currently taking all materials offered to it, with the knowledge that some may be extraneous, duplicate or out of scope. If the interest in NatHIC continues to rise, content may rise indeterminately and there will be a need for moderation of 'copy' in order to preserve the legitimacy of the resource. This will need to be carried out without bias by domain experts and knowledge management staff in the light of a number of factors, such as:

- content value to the domain
- scope of the topics and themes deemed appropriate
- usage rates
- copyright and license criteria

Value to the domain may change over time and will need periodic review. This could result in some material being withdrawn as no longer of significant worth or retained upon being confirmed as seminal and necessary to remain in the Collection.

Categorisation of materials will include evaluation by some, as yet un-constituted body, as relevant, in-scope and worthy of inclusion. In the immediate future, all received material will be stored. It will then be reviewed and processed for long term retention when appropriate criteria are determined.

The volume of copies submitted may require management against their usage; some key documents like national audit reports may be on frequent access by many people. A policy of retention for best quality copies being retained is already in operation, subject to estimated usage.

The mid-term requirement for moderation will necessitate drawing up rule-based policies for relevance, inclusion / exclusion and retention / withdrawal of material to ensure the integrity of NatHIC and its objective to preserve history and protect the future. This cannot be developed in isolation, but will be framed by the incoming material, potential user requirements and overall scope, and agreed by a representative editorial board, as yet un-constituted. In addition, for materials given to NatHIC, standard library protocols and existing mechanisms for clearing / establishing copyright and usage permission will be validated to determine their appropriateness; these materials include public domain materials, in-house reports etc., personal publications (for example student dissertations) or materials previously published elsewhere.

Future functionality

Facilities for self-loading of relevant publications may be useful; both by leaders in the field and for first line exposure of student theses and scientific papers. However draft terms and conditions will require definition and consultation, and processes for review will need to be operational to avoid / limit vanity publishing of dubious quality and contribution to the domain.

Grey literature, currently un-cited, ill-defined and transient may present a valuable resource to complement existing publications and complete the funnel plot described by Machan and demonstrate full coverage of knowledge across the domain. Further research will be necessary to validate this premise. In the interim, grey literature will be pursued, collected and reviewed at a later date.

Commercial bookshops around the world provide a service to new readers that indicates what the views of previous readers were on a particular publication. These views are displayed with books for sale on the shelves, but one suggestion is that a similar electronic facility could be added to NatHIC to allow users to comment on, or recognize similar materials on a topic that is in the catalog.

NatHIC aims to be inclusive and act as a portal where other established sources already have Health Informatics materials that are relevant. This will require planning and negotiation and will happen incrementally.

Critical success factors for NatHIC

Initially, success would be measured by a reduction in the number of historic documents being 'lost' to the community. Subsequently, it may be possible to monitor 'unrequited hits' for requested materials as an indicator of whether NatHIC is meeting community needs. As a proxy, an increasing number of formal arrangements with key stakeholders to routinely provide updated material will indicate increasing success.

The NatHIC has a linked informal blog [12] that will capture data on suggestions for new material and links. Monitoring unrequited searches and feedback will be reviewed periodically, so that NatHIC can target areas of interest that are currently not fully satisfied.

Results

To date, by early 2007, the Collection has over 1,500 contributions within an overall university library catalog of over 608 thousand items, including over ten thousand journals in the medicine and social sciences thematic areas. The range of media includes both contemporary hard copy and CD/DVD material and 'at risk' ephemeral media – including VHS videos and degrading paper. The 'at risk' material is being catalogued and steps will be taken to migrate it to viable media to capture the content.

Amongst the material provided are items which track the sequential phases of strategic development of NHS computing in England, specific business specifications of departmental and clinical systems, research deliverables from the sixties onwards and guidance on audit and information governance in both the NHS and European contexts.

The earliest material so far is - Berne, Eric (1968) Games people play: the psychology of human relationships [National Health Informatics Collection] Harmondsworth : Penguin, 0140027688. It is our belief that earlier material exists and is still being catalogued and prepared for NatHIC. HI in the UK is identifiable from 1961 when the first in-house hospital system was established in Manchester, although arguably, the NHS Central Registry pre-dates this as used in World War II to ensure unique patient identification. NatHIC is used by international cohorts of UCLAN HI students on Foundation degree to Masters courses; nearly 50 interested external parties have requested registration as Associates of UCLAN in order to access the NatHIC. This low number will increase as the body of content increases and as we attend events and promote the service.

Conclusions

The establishment of a national collection of Health Informatics material has been long overdue in the UK. It brings together resources that previously were (thought) lost or destroyed or considered to be of transient value. The advent of innovative electronic media makes this task feasible and sustainable in a manner not previously possible, and makes the National HI Collection accessible to a broad range of potential users. Usage over time will indicate its success. At this point in time, historic content is being added to the collection on a regular basis and arrangements with publishers for new materials to sustain

the Collection as a living archive are underway. In addition, newly published material will be incorporated as and when publishers and authors lodge reference copies with the Collection. The lessons learnt by this development will have resonance with any researcher who has previously not been able to source a required text on any media.

Acknowledgements

The authors thank colleagues working in and for the NHS, now and in the past, for their generous contributions to the content and development of the National Health Informatics Collection.

The EIPEN Project: Promoting Interprofessional Education in Health Professions

Joseph Liaskos, Antonis Frigas, Kostantinos Antypas, Dimitrios Zikos, Marianna Diomidous, John Mantas

Health Informatics Laboratory, Faculty of Nursing, University of Athens, Greece

Abstract

The Leonardo project under the name European Interprofessional Education Network (EIPEN) in health and social care, has been dealing with the challenges of Interprofessional Education (IPE). The EIPEN project tries to develop a transnational network of universities and employers in the six participating countries and at the same time to promote good practices in Interprofessional Learning and Teaching in health and social care. IPE provides opportunities for students and practitioners to learn with, from and about each other during qualifying and post-qualifying training and in their practice. IPE in health and social care includes the education and training of practitioners in human and animal medicine, dentistry, nursing, physiotherapy, occupational therapy, pharmacy and all other health professions including public and environmental health and health promotion, and social work. The outcomes of the EIPEN Project will provide means, material and guidelines for the enhancement of professional education in the multidisciplinary field of Health Informatics.

Keywords:

education, professional education, interprofessional education, multiprofessional learning

Introduction

According to the World Health Organization (WHO) Interprofessional Education (IPE) is identified [1] as an important component of primary health care. The Interpfofessional Education definition as given by CAIPE (Centre for the Advancement of Interprofessional Education) in 1997 [2] describes IPE as: “occasions when two or more professions learn from and about each other to improve collaboration and the quality of care”. The term multiprofessional education is also used to describe occasions when two or more professions learn side by side for whatever reason. The term interdisciplinary or multidisciplinary education or collaboration is referred to the combination and involvement of an assignment not necessarily working in an integrated or coordinated manner.

The interprofessional team in health has concentrated on two or at most three professions, primarily medicine, nursing and pharmacy. Interprofessional education has been invoked ever more frequently during the past thirty years to encourage collaboration in health and social care to help improve services, effect change and implement workforce strategies [3]. However, during the last decade, a renewed interest in IPE and an activity in health sciences programs appeared internationally. Inter-professionalism is very important while its importance is increasing; however there is not much literature on governance of Interprofessional Learning (IPL) [4].

Interprofessional education

Interprofessional education has been actively embraced in health professions since the 1950s, and in some cases earlier, and it is an evolutionary field of practice and research. It is seen as a way to develop collaborative practice among health and social care professions, and it plays a vital role in the patient-centred health services delivery approach. It contributes to collaborative practice and skills, aiming at patient safety. Teamwork is achieved through innovative methods of learning and practicing, improved ways of dealing with patient and technological complexity, enforcing professional relations and common understanding [3-7].

The implementation of interprofessional education is a difficult task for a various reasons: there are differences in prerequisites for admission to professional programs; the length of professional education; the extent and nature of the utilization of community and hospital resources for practice (clinical) education; students' freedom, or lack thereof, in the selection of professional courses; timetabling differences and conflicts across professional programs; faculty teaching loads; research interests of faculty; methods of administration within the various programs; and the powers vested in Deans of Faculties through statutory legislation, for example, through the power to appoint faculty members and to develop curricula [3,8].

Providing interprofessional learning experience that promotes teamwork and collaboration is a difficult task. There is a need to find academically acceptable mechanisms in order to measure the effectiveness of IPE activities. The existing attitudes of students, faculty and administration need to be changed in order to make IPE effective. The promotion of IPE as well as the measurement of its effectiveness requires that the students’ attitudes towards such work are assessed and evaluated.

Selected for best paper award.

Interprofessional education must confront particular challenges and needs seriously efforts in order to be successful. According to John H.V. Gilbert [8] these challenges include structural differences between faculty organizations; conflicting university and professional agendas; lack of adequate human resources to implement such programs, both within the university and across the community boundary; complex communication demands, within the university and with its community partners; rotation and replacement of team members; and lack of regular evaluation of interprofessional educational goals and programs.

IPE succeeds only when certain conditions are met: when the subject matter requires a team approach; when the effects of IPE can be clearly measured, for example, when critical reasoning skills are enhanced; when claims for resources to support IPE can be justified, that is, support for faculty and students is clearly necessary for success; when the skills being taught are within the competencies expected of a particular professional team; and when skills and knowledge can be explicitly taught and are clearly transferable, that is, those skills can be moved from one case to another [9].

Evaluation methods have to be developed in order to allow the assessment of the outcomes. These outcomes may include the patient, the process of interprofessional practice, individual professionals or agencies in which collaborations are carried out [10-12]. To exploit the benefits and outcomes of interprofessional education one must establish access to a wide range of resources of new knowledge and new skills. Many times, those benefits come through the shared respect and trust of the interprofessional partners who have been educated together in teams.

IPE and health informatics

Health Informatics is a multi-disciplinary field that deals with the collection, storage, retrieval, communication and optimal use of health related data, information and knowledge. The discipline utilises the methods and technologies of the information sciences for the purposes of problem solving and decision-making thus assuring quality healthcare in all basic and applied areas of biomedical sciences. Its domain covers computational and informational aspects of processes and structures in health care. Its aim is to study all the applications of informatics and computer science in Health Sciences (Medicine, Nursing, Dentistry, Biology, and Pharmacy) and health care. As a multi-disciplinary field it requires an educational approach aiming to collaborative learning. The different professionals who are graduates from specialised programs in health and medical informatics include physicians and nurses of different specialties, pharmacists, health care managers, computer scientists/ informaticians, engineers, e.tc. Moreover, practically all professionals in health care should, during their studies, be confronted with health and medical informatics education [13]. The development of educational curricula for Health Informatics follows an interprofessional approach.

In such an interprofessional educational environment (undergraduate or postgraduate), both teachers and students/ professionals from different disciplines have to be educated in a collaborative manner so as to develop the mutual understanding and respect among such multi-disciplinary groups, to enhance the existing and find new opportunities for shared learning and teaching, and advance the knowledge, skills, and attitudes of professional roles. For these aims, students will have to choose from a variety of learning activities such as team projects, which would provide opportunities for students to work together, tutorial courses focusing on a certain topic or area of health informatics theory or practice, exchange of experiences (e.g. observe team in action, discussion of real cases, placement of student or team in a real team of professionals in the clinical environment).

European Interprofessional Education Network (EIPEN) Project

The European Interprofessional Education Network in health and social care project, is supported and funded by EC Leonardo da Vinci Community action programme on vocational training (Project n^{o} 2005 UK/05/13/F/NT-162-335). It started on November 2005 and has two years duration until end of October 2007. The coordinator of the project is the Higher Education Academy Subject Centres, led by Health Sciences and Practice, based at King's College London (UK). In the network belong 16 partners from six countries. The European countries participating in the project are Finland, Greece, Hungary, Poland, Sweden, and United Kingdom, while the partners are universities, educational institutions, non governmental associations and centres related to interprofessional education [14-15]. From Greece two partners belong to the network: The Health Informatics Laboratory of the University of Athens and the, no budget holding partner, Greek Health Informatics Association (GHIA). The purpose of the project is to set up a network to develop and disseminate good practices in interprofessional education in health and social care in partner countries.

IPE provides opportunities for students and practitioners to learn with, from and about each other during qualifying and post-qualifying training and in their practice. IPE in health and social care includes the education and training of practitioners in human and animal medicine, dentistry, nursing, physiotherapy, occupational therapy, pharmacy and all other health professions including public and environmental health and health promotion, and social work. Interprofessional learning has been shown to lead to enhanced teamwork and health care. However, developing successful programmes and learning content and process is problematic. Thus partners desire to exchange teaching and management experiences as well as learning materials.

EIPEN has two interlinked aims: a) To develop a transnational, sustainable, inclusive network of people and organizations (universities and employers) in the six participating countries, and b)To share, develop, and promote effective interprofessional learning and teaching curricula,

methods and materials, good practices, for improving collaborative practice and multi agency working in health and social care. The model for network development is the successful UK Learning and Teaching Support Network, now the Higher Education Academy Subject Centres (www.heacademy.ac.uk), which uses a wide range of methods to disseminate and debate good practices in learning and teaching in Higher Education. The Subject Centres take account of the views of employers and other stakeholders, to sustain and extend their networks and to influence education policy. The network will be established over two years on a radial model. Each partner country will develop a website of resources and a programme of workshops and seminars that will link to a central interactive EIPEN web portal as well as regional and international events.

EIPEN goals

- Improved access to good practices, resources for learning and teaching, expertise, teaching materials and innovative case studies from universities, hospitals and other vocational training contexts in health and social care.
- A sustainable programme of events for presentations and debates concerning IPE.
- Dialogue with interprofessional education practitioners and peer consultation.
- New or improved sustainable national networks providing support for practitioners, teachers and students.
- Involvement of service users, students and policy makers.

EIPEN achieves these goals through the development of new networks within the health and social care sector through a programme of events at national, regional and transnational level:

- Interactive Web Portal with free membership registration, linked to national websites and resources
- Learning and teaching workshops and Seminars
- Transnational Steering Group Meetings
- International conference (2007 in Krakow)
- National learning and teaching resource databases linked to EIPEN portal
- Reports, presentations and publications
- Links with other International IPE groups

The products in two years includes the network, an interactive website with a resource database and a directory of people and organisation and discussion fora, and reports of national and international workshops and seminars on interprofessional training. The Transnational Network establishes and will be tested within 6 countries to ensure robust technology and systems and allow the design of procedures that will allow the resources of the network to be optimised. The aim of the project is to make the network available throughout the EU, but it is not possible to predict the specific longer term outcomes of EIPEN; these will emerge within the partnership. The web portal provides a facility for exploring other developments in health and social care practice and training, and the relationships being created increase opportunities for the exchange of ideas, staff and other partnerships.

Conclusion

IPE is innovative for professions, employers and education in health and social care. The innovation derives from the identification of opportunities for shared learning and teaching, the development of mutual understanding and respect among multi-professional and multi-disciplinary groups, the dissemination of interprofessional learning and teaching both in undergraduate and postgraduate education, and the advancement of knowledge, skills, and attitudes of professional roles. EIPEN develops new forms of networking within the health and social care sector for partners. EIPEN shares new products in the form of materials and methods for health and social care learning and teaching that will enhance the interprofessional education and learning in Europe.

Acknowledgments

EIPEN project is partially funded 2005-2007 by the European Commission as project No: 2005 UK/05/B/F/NT-162_335 in the Leonardo da Vinci Community action programme on vocational training. Project (network) partners are: Higher Education Academy, Health Sciences and Practice Network – King's College London (UK), Health Informatics Laboratory, Faculty of Nursing – National and Kapodistrian University of Athens (EL), Greek Health Informatics Association (EL), University and Polytechnic of Oulu (FI), Department of Mental Health Services – Oulu (FI), The Friends of the Young Association – Oulu (FI), Szechenyi Istvan University (HU), United Health and Social Institute – Gyor (HU), Department of Hygiene and Ecology – Jagiellonian University (PL), Occupational Medicine Centre of the Malopolska Region (PL), Karolinska Institute (SE), Centrum för Allmänmedicin Karolinska Intstitute (SE), The Primary Health Care Board – Stockholm County Council (SE), Centre for the Advancement of Interprofessional Education (UK), South West Peninsula Strategic Health Authority (UK), Steve Crane Consulting Ltd (UK).

Building ICT Capabilities for Clinical Work in a Sustainable Healthcare System: Approaches to Bridging the Higher Education Learning and Teaching Gap

Kathleen Gray, Jenny Sim

Biomedical Multimedia Unit, The University of Melbourne, Australia
Centre for Medical and Health Sciences Education, Monash University, Australia

Abstract

There is a recognised gap in information and communications technology (ICT) learning and teaching in higher education for entry-level healthcare professionals. This paper proposes a research model for understanding the dimensions of this gap. We describe methodological approaches to understanding present practices, identifying levers for change and learning by doing. We discuss issues faced in getting started and sustaining momentum on the research that is an essential prerequisite to effectively build the ICT capacity required by the clinical workforce in a sustainable healthcare system.

Keywords:

clinical informatics, competency-based education, education research, interdisciplinary communication, professional education, teaching.

Introduction

There is a recognised gap in information and communications technology (ICT) learning and teaching in higher education for entry-level healthcare professionals, and it needs to be bridged in order to build the capacity required by the clinical workforce in a sustainable healthcare system. Despite advances in educating specialist informaticians, in offering informatics electives to pre-qualification healthcare professionals, and in mapping details of ICT capabilities for healthcare professions, fundamental broadly based workforce capacity is not yet being established.

The contribution of ICT towards building a more sustainable healthcare system cannot be achieved by specialist informaticians alone, and relies upon active use of ICT capabilities in the professional practice of all clinicians. Clinical professionals' development of essential informatics capabilities is of local, national and international significance for evolving professional practice and education standards, and reform of healthcare system operations and management. Health informatics is an increasingly influential part of the working environment of "clinical staff including doctors, nurses, pathologists, pharmacists and other clinical professionals" [1]. The informatics capabilities of such staff are also a matter of interest to the public, as stakeholders in the healthcare system; increasing integration of ICT into healthcare has important implications for the quality of care, and for patient privacy and safety.

Improving the implementation of ICT in the healthcare system cannot be done only by providing these capabilities as optional extras for study by entry-level clinical practitioners; rather, it is necessary to embed informatics learning thoroughly in other aspects of professional learning and development [2, 3]. Examples of current educational interest in the learning and teaching of such capabilities in various clinical professions include allied health [4], dentistry [5], medicine [6], nursing [7] and public health [8]. But often such capabilities are addressed only in stand-alone ICT modules or elective units of study offered to students in their basic clinical training.

Nor can the healthcare system's need for technological transformation be met by learning and teaching capabilities simply profession-by-profession for clinicians. Calls to adopt a collaborative and multidisciplinary approach in promoting good health and well being [9] and to build ICT capacity across the entire health workforce [10] underscore the need for cross-professional learning and practice. ICT is recognised by a number of health educators to be an area of capability well suited to collaborative learning across professional boundaries [for example 11, 12].

Methods

A comprehensive research agenda is required to assess and address the higher education learning and teaching gap just described, so that we know what are the most promising approaches to pursue, in order to bring about the necessary educational change. This section proposes a three-dimensional model of the terrain to be bridged; it suggests a methodology for understanding the present situation, identifying levers for change and acting deliberately in response to this gap.

Present practices

One dimension of the gap is our lack of detailed knowledge about present practice in ICT education. It is important that those who educate future clinical professionals access and share research into "understanding where we are now … in order to clarify what practical steps are needed to move forward into the future" [13].

Clarifying the present situation with regard to ICT learning and teaching can provide important baseline data to allow prioritisation of research projects and evaluation of the effects of interventions. Key aspects of research to be done in this area include:

- Research into current roles / uses of ICT in educational settings for entry-level health professions: Across higher education, "There is enhanced use of educational technology … but all too often this emulates traditional didactic teaching and testing instead of promoting student curiosity and autonomy… In other words there is too often a poor alignment … between what is taught and the competencies students will need in their later lives and work settings" [14].
- Research into expectations about ICT as expressed in curriculum standards and professional accreditation processes: "Curriculum documentation can be read as giving in principle scope and support for the teaching and learning of essential clinical uses … However, documentation does not systematically address principles or processes for learning experiences that would scaffold or guide a student's transition …to those that are necessary or desirable in contemporary clinical practice" [15].
- Research into ICT applications in use in various clinical workplaces where students do their placement learning and hold their first jobs after graduation: A reality check is required to compare recommendations re informatics knowledge and skills that all clinical professionals *should* have [for example, 16] against the environments in which they actually work.

Levers for change

Another dimension of the gap is our lack of detailed knowledge about factors influencing ICT learning and teaching in higher education. We can locate obstacles to and levers for bridging the gap if we have a better understanding of the current dynamics of learning, teaching and educational provision:

- Understanding learning, especially understanding what learners need to be taught formally versus what they already know: For example "very little empirical research has actually questioned the Net Generation about their experiences with technology and worked with educational practitioners to determine the implications this has for Higher Education" [17].
- Understanding teaching, in particular the attitudes and experiences that determine orientations of key staff such as degree and year-level coordinators: For example, academics teaching core aspects of medical degree studies may find informatics "difficult to conceptualize" as a field of study and they may be equivocal about its inclusion in professional training [18]; and a nursing educator asks, "How can we expect faculty to transform nursing education for a type of practice that they have not experienced?" [19].
- Understanding what is involved in the provision of higher education, notably the pressures of globalisation, massification and privatisation on educational quality, and thus issues in competition with ICT education for attention in the operation of every clinical degree. In an example taken from physiotherapy, "The issue evoking most concern and comment is that of the ability of schools … and their professional clinical colleagues to continue to deliver appropriate clinical education within current resource constraints" [20].

Learning by doing

Another dimension of the gap is our lack of detailed knowledge about educational development prospects. Educational change is continuous and complex, and it is important that we recognise and capture the contribution of 'learning by doing' to what options there are for integrating ICT education into mainstream curriculum, and for finding interprofessional and inter-institutional ways of educating for ICT capabilities. This includes understanding what may be achieved by:

- Designing and implementing new learning and teaching resources and environments, such as plans "to integrate an entire enterprise-wide, electronic health record (EHR) system into the teaching curricula of nursing, physicians, pharmacists, and allied health schools, as well as health informatics and computer science" [21].
- Taking educational leadership roles in macro curriculum reform. Current health workforce shortages are producing many alternative scenarios for ways in which universities might partner with health services to provide frameworks for "experimentation and responsiveness in terms of preparing new types of health workers" [22].
- Strengthening research-led teaching or the teaching-research nexus, so that entry-level degree programs are appropriately informed by research into informatics – for example, there are a number of instances of research into using wireless handheld devices in clinical practice now being translated to enrich clinical teaching [23].

Such a research agenda needs to take a grounded theory approach. That is, it needs to iteratively and comparatively use data obtained from mixed methods of research - analysis of research literature and public documents, field observations and interviews, empirical studies; action research; individual and group evaluation by research participants - to provide an evidence base for the design and implementation of ICT learning and teaching for professional practice that will lead to systematic and sustained educational improvements. This approach is "uniquely suited to form the basis of research programmes that arise from theory grounded in the [health sciences] education experience, and then build toward implementation of practical educational innovations" [24]. Such an approach to research addresses recommendations for structuring clinical education [25], for developing authentic learning [26], and for supporting successful implementation of interprofessional education for collaborative practice [27]. This approach to research also accommodates the concept that educational development can overcome aspects of frag-

mentation and build a new professionalism in academics' working lives, through sponsoring a series of critical conversations [28].

Discussion

Preparing to advance upon a three-dimensional model using a toolkit of mixed methods to fill a major gap in clinical education knowledge and practice is a daunting prospect. It is no wonder the gap remains wide. In this section of the paper we review issues of when and where to start and how to sustain momentum, and we highlight some overarching considerations.

Of course, such work has been started, by many redoubtable educational researchers and practitioners, and has been in train for some time, however it continues to be hampered by issues of:

- The relatively low status of research into teaching and learning, especially in comparison with other research agendas in health and life sciences, and the consequently weak coordination and recognition of research in this field: this may be illustrated by the anomaly of strong emphasis on evidence-based practice in clinical work alongside its near absence in teaching and learning.
- The challenge of planning and resourcing complex ICT education research that is not just do-able, but meaningful in scope and scale, in order to make any significant difference to learning, teaching or curriculum: There are a myriad of political and logistical pros and cons to be weighed up in working on projects as a local initiative, versus on a state level or nationally, and / or in doing comparative studies nationally or internationally.
- The never-ending quest for sustainable long-term research partnerships with stakeholders external to the education system, such as ICT developers and vendors, healthcare agencies, health system funders: how is it possible to establish, maintain and evaluate these partnerships, and how to sustain this commitment alongside the full academic teaching and administration workload of many educational researchers?

Conclusion

Our view of the research to be done, the approach needed to bridge the knowledge and practice gap and the challenges faced in taking on this agenda rests squarely on eight key change lessons for higher education [29]:

1. "There are far more options for improvement or innovation than there is time or resources to address them."
2. "Change is not an event but is a complex and subject learning / unlearning process for all concerned."
3. "Enhancements in learning programs generate a need for improvement in the systems and infrastructure that underpin them."
4. "The most successful changes are the result of a team effort in which the most appropriate and best positioned people are involved in a process of action learning."
5. "The change process is cyclical, not linear."
6. "Change does not just happen – it must be led."
7. "Change is a mix of external forces and individual action."
8. "We must look outside as well as inside for viable change ideas and solutions."

This research needs to have a broadly-based view of the terrain, a robust methodological framework and mechanisms to share findings across boundaries and communities. Stakeholders must work together to keep this research agenda in the forefront in teaching and learning quality and research quality forums; in professional and industry forums on quality of care and workforce planning; in relevant non-governmental organisation and government forums. This work requires coordination and commitment among various stakeholders at multiple levels, and it requires substantial resources to ensure outcomes that are of significant benefit to the community, whether locally, nationally or internationally. Compounding the difficulty, Australian national classification systems for research fields do not enable ready identification of health informatics education research or give such research high visibility. However, it is only through seeking change in these conditions we will see real progress being made to bridge the higher education learning and teaching gap in building ICT capabilities for twenty-first century clinical work in a sustainable healthcare system.

The need for informatics education for non-specialists has been obvious for many years now [30, 31]. Our aim in this paper is to encourage the growth in strategic collaborations to take on all aspects of the associated research agenda over the next few years, in order to improve approaches to developing essential informatics capabilities in the entry-level education of clinical professionals. We welcome enquiries and approaches from others interested to work with us in this endeavour.

The Development of an Online Clinical Log for Advanced Practice Nursing Students: A Case Study

Jeffry S. Gordon [a], Ryan McNew [a], Patricia Trangenstein [a]

[a] *Vanderbilt University School of Nursing, Nashville, TN USA*

Abstract and objective

Three years ago at the Medinfo conference a prototype version of a clinical log for nursing students at Vanderbilt University was demonstrated. The purpose of the log is to document the types of clinical experiences the students are participating in as part of their academic program. We collected log data during that first year and received ongoing formative feedback from both students and faculty regarding its current feature set and desirable features for future implementations. Most of the requested new features have now been implemented. This paper describes some of the latest features of the clinical log, the advantages and disadvantages of ongoing development versus acquiring commercial products, and the procedures and results we have put in place to gather from faculty and students the features they want to see in the log. This paper also documents some of the data from early data mining.

Introduction

Vanderbilt University's nursing curriculum is an Advanced Practice program designed to turn out Nurse Practitioners at the master's level in the following specialty areas: Acute Care, Adult, Family, Pediatric, Acute Care Pediatric, Midwifery, Psychiatric/Mental Health, Women's Health, and Neonatology.

Five years ago the PNP specialty faculty approached the informatics group about building an online clinical log to track their students' clinical experiences. They wanted a web-based version because it would provide more timely data to the faculty on the types of experiences their students were having. Until then, the students completed a notebook based paper log, sending it in twice a semester, and completed an op-scan questionnaire that was completed at the end of the semester. Op scan questionaires became increasingly popular in the early 1900s as an alternative to paper (Witzke et al., 1990) however, neither log type provided timely data. Notebooks could be lost in transit and it created a backlog several times a semester for faculty who had to read, make decisions on, and comment on the clinical experiences the students were having. McVeigh (1997) notes that paper logs are very inefficient. The faculty wanted the ability to check student experiences nightly to make sure there were no experience gaps. Gaps, if found, could then be dealt with in a timely manner (Alderson et al., 1999). They wanted the students to look for specific types of cases and log them as documentation that they had participated in them. The initial effort was rather primitive but it did provide the students with the ability to nightly log their clinical experiences and allowed their instructors to comment nightly on these experiences. Within two months, two other specialties (ANP, FNP) requested similar logs for them. This clearly escalated the development from "proof of concept" to the production of a professional quality web tool.

Currently the Vanderbilt clinical log supports students in 8 of the 9 specialties and will cover all 9 specialties next year. Initially we attempted to make all the specialty logs very similar. This would not only aid in coding the logs but it would make cross specialty comparisons a do-able procedure. Unfortunately, the significant differences in specialties and specialty requirements argued against keeping them very similar and as the years have progressed, even the basic features of the logs themselves have significantly diverged.

Methods

The initial logs were created by meeting with faculty in the specialty areas, demonstrating our existing log, and working from that. The datasets in the logs themselves were composed of generic data (time of patient meeting, type of insurance, gender of patient etc.), radio buttons indicating the level of participation in the encounter, checkboxes geared to the specific activities within the specialty, ICD9 code area, and a comment area. The student would treat each patient encounter as an individual record by entering the data above. The data could then later be queried by the student or the faculty member and summaries could be printed out. The faculty member could then write comments back to the student that would be included in the log. For all practical purposes, the only initial differences by specialty were the checkboxes identifying what procedures the student participated in.

After the first year, both faculty and students requested a large numbers of new features and additions they wanted

in the log. One area of immediate concern related to the checkboxes themselves. Standards and competencies from professional organizations were used to create the procedure checkboxes that was at the heart of the log. The log was created, to a great extent, to be faculty independent. It would be unacceptable to have a faculty member who was responsible for working on the log to leave, only to be replaced by another faculty member who wanted a completely different set competencies and experiences documented. The faculty examined the National Organization of Nurse Practitioner Faculties (NONPF) competencies in their specialty areas and designed their competency checkboxes from these competencies. Since NONPF was only creating some of those competencies during that time, it became apparent, particularly in the Psychiatric/Mental Health specialty that these checkboxes would have to be revisited after a year.

Results

We had three goals in the development of the clinical log.

1. The system had to be powerful enough to collect the right kinds of data. It had to meet the needs of the students and faculty and reflect the standards set by the professional organizations.
2. The system had to be easy to use. If it was difficult to navigate or cumbersome and time consuming to use the students would object. The faculty did not want the students to think of this as busy work.
3. The system had to be extremely reliable. Many of these students are not computer comfortable. They would never know whether the failure was at their end or our end but it would not matter. The frustration would be evident.

We met with each specialty of students three times formally during the year and with the faculty in each specialty at least one time formally per year. We made sure that students and faculty felt comfortable enough to approach any one of us at any time, through face to face meetings, email, telephone, or instant messenger.

The primary concern of the specialty faculty was to create a system that was easy to use by both students and faculty and where the students would not be bogged down nightly recording data as busy work. It is well documented in the literature that students are concerned about being overwhelmed with busy work while completing a log (Bardes et al, 2005) The faculty requested that a record should take no longer than 60 seconds to enter, and short of lengthy comments that goal has been met. The faculty also wanted a way in which students could flag certain records as important for their instructor to view. A checkbox was created that allows the student to indicate to the faculty member that this is a record of consequence. The students wanted to know when faculty commented on a specific encounter so an indicator was created on the student side showing which specific records had received faculty comment. The faculty members could even select the color of ink of the comment and tie that color to the flag indicator on the student side. While we assigned no importance to the color, and most faculty continued to write their comments in black, the additional color feature was a useful way for specific faculty to set priorities on comments.

The system had to have an easy to use login procedure. It was surprising that even well into the semester, students would forget their login names and passwords. In response, we created an email utility that would email them their lost password, but many students refused to use it. Since the university has a common username and password login for email, student records, and its course management system, we elected to switch the login procedures to that and this year not one student has contacted any of us about forgotten usernames and passwords.

System stability was a very critical feature. Many of these students and some faculty do not claim to be computer comfortable. Failures for any reason would cause them to balk at using the system and the students would then pressure the faculty to return to a paper log environment. Other than students forgetting their passwords, the system has never been down in three years. On several occasions faculty could not initially see a particular student but that was because the procedure we used to identify them by specialty incorrectly placed several students into the wrong specialty. Once those were identified (7 in three years) the problem was fixed manually. To summarize: The system had to be easy to use, powerful enough to provide students and faculty with the data they needed, and it had to be stable.

After about a year into development, several commercial products became available and we offered to consider switching to one of those applications... Faculty however, did not want to switch. The reasons they gave were: “we already know this log and it works.”, “why purchase something when we already have what we want”, “I like that I can make recommendations for changes and they will be implemented right away” (we quickly learned that rapid turn around on requests built strong loyalty for our efforts), “if our students have problems they know exactly where to get help”. Those were balanced against reasons for switching to a commercial product: We could get out of this business and focus our development resources elsewhere and there would be greater opportunities to share data across schools. As much as it was discussed, neither of these reasons was compelling enough to get the faculty to adopt a commercial product and the team realized that by customizing the log to their specialty requirements, we were building a product that they would use far into the future.

While great efforts were made to try to at least keep the logs of the various specialties parallel, it became apparent that this was not going to be possible. The Psychiatric/Mental Health specialty is an interesting case study on how difficult it became to keep the logs in synch. First, the PMHNP specialty uses DSM codes, not just ICD9 codes. Secondly, the manner in which they interact with their patients during their clinical hours is substantially different. Typically the other specialties’ students see any given patient one time. It is extremely rare that they would see a patient twice during their clinical experience. For these specialties, each encounter was equivalent to seeing a new patient. The PMHNP specialty’s students, however, see the

same patients over and over again week after week and they wanted the ability to "tie" the common records of a particular patient together. Retrofitting the log with this capability presented an interesting collection of challenges but they needed this for two reasons. It would make it easier to document patient progress over time if they could aggregate a specific patient's records in one place and they wanted a way to save their students' time by eliminating the need to check a host of demographic boxes on the same patient each time when the contents of those boxes essentially changed little from encounter to encounter.

Initially we provided a comment field for students to write their clinical comments on a particular encounter but the 5000 character limit was quickly discovered as inadequate for the PMHNP specialty. Furthermore the PMHNP faculty wanted their students to work off of a Microsoft Word created template that was not possible to code into the system. We then created an uploader that allowed the student to write their clinical comments in the Word template, save it under a specific record name that tied it to a particular encounter, and then upload the file to the server. The faculty side was then flagged to inform the instructor that a file attached to a specific encounter was available for viewing and comment. This year the PMHNP faculty wants the students to audio record the encounter. We have now created a methodology for recording the audio on their PDA, converting the file to mp3, and using the same uploader to attach the audio file to the appropriate encounter record.

Since certification requirements differ considerably between specialties, we had to create customized ways of tracking time and activities in an encounter. The Family PMHNP students for example, need to separate and track direct contact hours with patients under 18 versus direct contact hours with patients 18 and over, indirect hours related to time spent preparing for an encounter, and supervisory hours related to time spent conferring with a supervisor. Students were keeping this data on paper separate from the log. The instructors approached us with this issue and we immediately put it into the log. Other specialties, such and Midwifery, on the other hand, needed to track the number and types of births the student participated in.

Students approached us very early on and complained that they were in fact entering data on each patient twice: Once on paper after the patient had departed, and again online in the web interface that evening. Garrett (2006) identified the same issue. The students wanted a way to only enter data once and so we came up with a PDA solution to the problem. The student would enter the data immediately after the clinical encounter on their PDA, then they would synch the PDA nightly to avoid losing data. Once a week that synched data would be uploaded to the server and installed into the online database. We decided to force each specialty to use the web version only for one year, and then when the checkbox choices stabilized we would build them a PDA version. Constructing the PDA version would be difficult and we wanted to avoid making major changes in it each year. Currently we have PDA versions for 6 of the 9 specialties.

This year the PDA usage with the log has been as follows:

Table 1 – PDA Users

Specialty	Students	PDA users	Percent
ACNP	43	9	21%
ANP	35	6	17%
FNP	62	11	17%
PNP	34	19	56%
NMW	19	11	58%
PMHNP	28	0	0%

While 100% acceptance of the PDA solution was never expected, the relatively low percent of students using this technique was somewhat surprising. Garrett (Garrett et al., 2006) points out that the inherent restrictions on PDA can result in limited use. However, even with low numbers, the allegiance to this approach by the students practicing it was substantial. If a student started using the PDA environment to record their data, they stuck with it week after week.

Students gave a number of reasons why they chose not to use the PDA approach once they were given the option.

1. While PDA purchase was strongly encouraged and, in some cases required by each specialty, some students refused to make the purchase.
2. Some students balked at the $40 charge to purchase a PDA database program needed to make the PDA clinical log work. They opted to stay with the free web version.
3. Installing all of the software on the PDA to make it work was rather onerous. Some students claimed they couldn't get over that hump even though we created a web based Camtasia presentation that explained it in detail.
4. PDAs can be intimidating, particularly when they don't work the way the user thinks they should work and some students therefore just don't like PDAs.
5. Almost half of the students in the PMHNP program, for example, who commented on the PDA problems in their course evaluations, alluded to the lack of screen geography or difficulty in navigating the PDA clinical log application due to small screen space. This suggests that a tablet computer might overcome their reluctance here.

Last year none of the PMHNP students elected to use the PDA for data collection. When we asked them about that it was clear that the primary feature of the clinical log that they regarded as most important was the comment area and the corresponding ability to upload a Word file on the encounter to the record (Over 75% of the students were regularly uploading Word files with each log entry as

opposed to using the comment area in the log.). The PDA piece actually got in the way of their ability to do this. Comments of substantive length are cumbersome to write on a PDA and uploading a file works best when it is added to the record immediately after the record was created. Since PDA records were only uploaded once a week, the delay became an issue for these students. However, they do use the PDA to audio record their encounters. What this demonstrates is that people will use the technology they need to do their job as long as the technology helps them do their job, but they will not conform what they need to do to accommodate the technology if they perceive the technology is getting in the way. Since the PDA clinical log got in the way of the PMHNP students' ability to record the necessary data, they elected to just not use that capability.

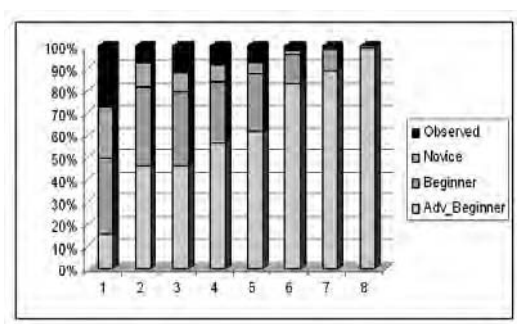
Perhaps the high percent of PDA users in the PNP and NMW groups is due to interested technologically literate and supportive faculty members who modeled behavior by using the PDAs for a variety of experiences in class. Since one of those faculty members has since left the institution, it will be interesting to see whether those numbers hold this year.

Early on in the development the specialty faculty members were asked what types of data queries they would want for both themselves and their students. It was necessary that they be very careful what they asked for because these queries are cumbersome to write. Because of limited resources, it was important that they not request queries they ultimately would not use... Rather than develop a series of queries the team created a tool to output the data into a spreadsheet table (Excel format) and taught the faculty and students how to analyze the data from there. The faculty appreciated the opportunity to learn Excel since they felt it could assist them in their research. They also said that since their students are becoming advanced practice nurses who will participate in research they too should learn Excel as a research tool. However, even with hands-on experience learning Excel in the computer lab, some students were just having a lot of trouble picking it up after a single training session. In response, the team created a web based animated training module using Camtasia and made that available on demand. Students could then go through the narrated training module whenever they were working on their analyses. In two of the specialties, the faculty showed the Camtasia presentation in class. The students commented that with the Camtasia created presentation, preparing the final analysis was very easy. The NMW specialty faculty, however; decided they wanted to create special queries outside of Excel. One of the students in the NMW program had an undergraduate degree in Computer Science and offered to program the queries. She was granted access to the DSN name, database tables, and variable names. She said she appreciated the chance to renew her skills in the area. Within several months she had a variety of queries programmed directly into the environment. This year, the NMW faculty wanted a significant number of changes to their log and we were concerned that the queries the student developed would no longer work. However, her code was well documented and it was easy to make the necessary changes to it. The other specialties have now seen the NMW queries but, much to our surprise, have not asked for them, even though we have offered building them. Apparently they still prefer the Excel approach and appreciate that we are teaching this lifelong skill to their students.

Students report that by using the output from the clinical log as a portfolio, they appeared to have an advantage in searching for the positions they wanted. One psychiatric student was able to demonstrate the types of patients he had worked with to such a degree that they offered him the position immediately. Others reported similar encounters. Several students asked if we could keep their accounts in the log active because they wanted to keep an ongoing portfolio of their more interesting cases and wanted documentation to support their activity.

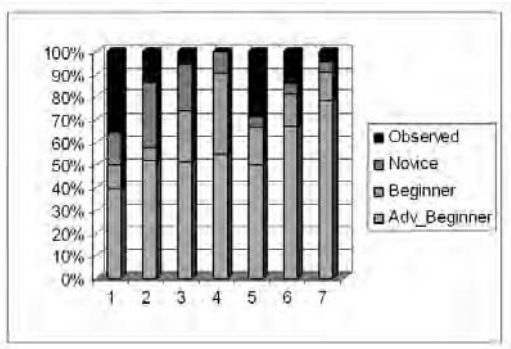
Faculty are now beginning to discover how to data mine the data tables and are seriously looking at the kinds of experiences their students are having across years. The overall data shows that the students definitely do gain clinical experience and confidence through the year. In the log the students evaluate their involvement in each encounter on a 4 point scale: (Observed, Novice, Beginner, up to Advanced Beginner with descriptor adjectives to enhance reliability of assessment). Figure 1, below, from the Family Nurse Practitioner (FNP) specialty, clearly shows that the students move, almost linearly from mostly observing to becoming more advanced in their participation over their 8 month clinical experience.

Figure 1: Type of involvement per encounter by month (FNP)



The relatively non-linear shape of the curve, below, in the Acute Care Pediatric Nurse Practitioner (PNP-AC) specialty is now serving as the basis for discussion on the types of clinical experiences this specialty is having, even though the general trend is toward more advanced experiences. Why, for example, is it relatively flat from months 2 to 5?

Figure 2: type of involvement per encounter by month (PNPAC)



We are now going to embark on a serious look across years and across specialties to guarantee that we are meeting the needs of the disciplines. We currently have approximately 490,000 individual patient encounter records in the system spanning the three years. As we add our final specialty and offer to make the log available to our partner that teaches the anesthesiology specialty, we anticipate adding over 200,000 records per year to the system.

Our next steps in the development process consist of altering the procedures we use for the PDA side, exploring alternative input devices, such as the intelligent pen and java enabled cell phones, and stabilizing the type of data collected to better allow for year to year comparisons. At the request of the program faculty, the PMHNP PDA log will be abandoned. Instead they want us to facilitate using the PDA to better audio record the patient encounters their students have and we will spend our development time with them promoting that. The rest of the specialties want the PDA piece streamlined with the data available for faculty review nightly instead of once per week. We are currently looking at two different technologies to accomplish that task. Finally, there is the ongoing conflict between standardizing the data to facilitate program to program evaluations and the customizing each specialty area to more exactly meet the needs of each particular program. This next year there will be an attempt to create more standardization where possible, but after that we are going to let the data fields stabilize for about two years to permit year to year comparisons and analysis.

Conclusion

The development of the clinical log has been an exceptional team building experience between faculty in the specialty areas and the informatics faculty and staff. Creating a professional quality "home-grown" log has given the school an excellent example of what the skills of the informatics area can accomplish. The faculty has been very pleased with the quick response they get when they want a new or improved feature and now rely on the informatics team for all of its technological needs. In return, we has learned a great deal about what works and what doesn't with students by specialty area and has developed a close professional relationship with the specialty faculty. We have been surprised at how rapidly the faculty has adopted the log. Based on prior work we anticipated relatively long lead times to change the culture (Nierenberg et al., 2007) but that turned out not to be the case. The faculty is now beginning to data mine the log to improve the clinical experiences of their students and perhaps alter their clinical content as well as modify the focus in their didactic teaching. Program alteration does not come automatically, however, and effort must be made to use the logs to improve the structure of student learning (Dolmans et al, 1999) This experience has translated into many other additional projects. We are now using the log technology for a grant supported cell phone based messaging system to encourage smoking cessation. We have created many online assessments, surveys, and questionnaires for the school and associated organizations. Finally, we are exploring new technologies, (such as intelligent pen based data collection systems and java enabled cellular phones) to accomplish many of these tasks.

Abstract

Neonatal Intensive Care Units (NICUs) are foreign and intimidating to parents of premature infants. The high levels of anxiety and stress they can produce needs to be reduced by thoughtful advice from healthcare providers (HCPs), to educate parents about their child's condition. Unfortunately time constraints often limit HCPs to only a few minutes with each baby's parents daily – only enough to convey critical information at a high level and with limited depth. Parents searching for more detailed information themselves in the literature over the web have sometimes reported disappointing experiences. We are proposing to improve parental education by patient-centric web methods leveraging the electronic patient record with internet and cell phone technologies. This can be an important informatics resource, complementing and enhancing face-to-face communication through personalization of education and advice to the parents.

Keywords:

Neonatal Intensive Care Unit (NICU), Personalized Parent-Patient (PPP) model, personalized parental education, electronic health record (EHR), Health Care Providers (HCPs)

Introduction: NICUs and Parents

The NICU experience is an emotional and confusing time for parents; what many families expected to be a time of joy and happiness has turned into an event filled with uncertainties. Many parents entering the NICU feel overwhelmed by the intensive care unit environment, including the technology, language used, and the pace of events [1,2]. This, coupled with their own sense of loss of expectations for the birth and future of their child, can lead to miscommunication between staff and families. What may seem "normal" to the NICU staff, can feel anything but normal to the family. An important way to make the experience most constructive is to develop a trust relationship between families and their HCP through effective communication [3,4,5].

The informational asymmetry that exists between the medical staff and their patient families is a source of anxiety [5]. While every individual has their own communication and information processing styles, what is important to parents is that they have access to all of the information that they want to have, when they want it, and that they be allowed to absorb the information in their own time. Withholding information, even under the pretense of sparing the family pain, or perhaps unnecessary anxiety, does not create a trusting relationship between the staff and the family [2]. The Bayer Institute for Health Care Communication identifies education along with empathy, engagement, and enlistment as one of the key factors of successful communication. Learning and understanding is best done in steady short segments, rather than episodic large segments [9]. Benefits of an educated parent are less anxiety, less depression, shortened NICU stay, and increased satisfaction with the medical staff care [3-7].

The high acuity nature of the NICU prevents the HCP from spending the necessary time needed to provide optimal patient education. In one study, parents feel that important information was not relayed satisfactorily almost 50% of the time (i.e. either too much, too little, or not explained at all) [10]. We propose a solution for optimizing parental education in the NICU by leveraging technology to educate parents 'on the fly', engaging the HCP only for critical tasks such as content verification before sending to the parents. The system should map existing information in the EHR to existing peer reviewed knowledge resources. Our system (1) matches personal content in the EHR to existing knowledge resources (KRs), (2) presents those KRs to HCPs for approval before sending them to parents via a secure web portal, and (3) uses cell phone technology to alert HCPs and parents of new information available for sending and viewing, respectively. This strategy aims to enhance the personal meetings between HCP and parents by (a) preparing parents before the meetings with background information, (b) giving additional information that may clarify questions that parents may think of after the meetings but are unable to ask HCPs immediately, (c) expediting communication between the HCP and parents regarding important and unexpected issues that may arise during the baby's clinical course.

Table 1 Neonatal Clinical Scenario

Event		Action by HCP using EMR in the NICU			EMR Test results
Date Time	(#) Description	Add to patient's problem list	Orders	Notes	
Day 1 8 AM	(1) Infant delivered by normal spontaneous vaginal delivery with 1, 5 and 10 minute apgar scores of 9/9/9. Prenatal labs significant for GBS+,Hepatitis B unknown. Baby with respiratory distress.	Prematurity, Rule out sepsis, Hepatitis status unknown, Surfactant Deficiency Syndrome	*Test Order:* hemogram, blood culture, c-reactive protein, chest x-ray *Med Order:* Ampicillin, Gentamycin,Hepatitis Immunoglobin /vaccine	CPAP	
9 AM	(2) CXR c/w RDS,give 40% O_{2}		*Med Order:* Surfactant	Intubation*	
1 PM	(3) Hypotension, wide pulse pressures,		*Test order:* Echocardiogram		
3 PM	(4) Hypotension		*Med order:* Indomethacin		*Echo* - PDA
Day 2 8 AM	(5) Normotensive,Infant extubated and placed on CPAP			Extubation to CPAP	
1 PM	(6) Started feeds- breastmilk		*Feeding order:* start BM 1 ml every 3 hours via NGT		
Day 3-20	(7) Increased Apnea episodes Jaundice	Apnea Jaundice	*Med order:* Caffeine, Phototherapy		
Day 21 8 AM	(8) Routine hemogram significant for anemia	Anemia			Hematocrit = 25
Day 49 8 AM	(9) Ready for discharge		*Order:* Discharge		

Methods: Clinical scenario

Setting. Currently, physicians in our neonatal intensive care unit at the Bristol Myers Squibb Children's hospital enter patient information into an electronic health record system named NeoData, by Metasoft Systems, Inc. The Eclipsys 3000 TDS system is used to enter orders and view test results. Patient problem lists, orders, and test results will be obtainable by our software system. We will illustrate how our system can help educate patients' parents in our NICU. Table 1 highlights events for a typical neonate over a timeline spanning three common phases of a patient's hospital stay: Admission, Interim, Discharge.

Synopsis. TJ is a premature baby boy born to a 39 year old mother at 29 weeks gestation. The apgar scores are 9 at 1, 5 and 10 minutes after delivery. His mother's prenatal laboratory result is positive for Group B Streptococcus and her Hepatitis status is unknown. TJ's immediate medical issues are Surfactant Deficiency Syndrome (also known as Respiratory Distress Syndrome) and Patent Ductus Arteriosus, resulting in respiratory distress and hypotension. An immature immune system makes TJ vulnerable to infections;jaundice and apnea also occur. His stay in the NICU also involves extensive routine care issues that support proper growth and maturation until discharge.

Admission period. TJ's admission period (day 1-2) is one of the most clinically telling, data intensive and anxious moments. Perhaps the most important and longest HCP-parental meetings occur at this time, typically lasting 30 minutes. During this time, TJ's HCP team must not only orient his parents to the NICU environment, but also discuss prematurity and its implications, its many acute events, and be sensitive to the parent's level of confusion, stress, and medical unawareness – in TJ's case, the numerous topics are respiratory distress, sepsis, antibiotics, various diagnostic lab tests, and Hepatitis prophylaxis (event 1). The nurse at the meeting must review general nursing procedures and routine regulations as well as the operational rules of the NICU. Not surprisingly, when parents are later asked about what was discussed, many can not recall key points of the content [8]. Reasons for difficulties in knowledge retention are (1) too much, too soon, too complicated (2) emotional interference, and (3) lack of HCP follow-up.

A detailed discussion of all of TJ's acute clinical issues (prematurity, sepsis, respiratory distress syndrome) would be overwhelming. An HCP-given high level overview in lay terms of current clinical issues and forthcoming expectations is effective for the short term, but needs to be followed up by detailed information and opportunities for parents to ask follow-up questions after 'digesting' the news – all done using a family centered approach [13]. Our system enables ongoing delivery of important information, complementing what is learned during these meetings, especially the initial one, so that they can be better prepared to ask important questions in subsequent meetings.

Interim period. The interim period can be both long and unpredictable, testing the emotional fortitude and patience of parents and HCPs. In most cases, meetings with the HCPs are sporadic and dictated by clinical events rather than regularly scheduled updates. In one study, only 26% of the surveyed parents report talking to the neonatologist on a daily basis [10]. Without meaningful and well timed dialogues with HCPs, parents can easily be misinformed by the internet and non peer-reviewed literature. A study by Dhillon et al reveal that only 10% of parents feel medical information found on the internet is reliable and up to 24% found the information to be over-frightening [12]. Shortly after birth, TJ's respiratory distress worsened and prompted emergency intubation and placement on a ventilator. Soon he became hypotensive (events 3-4) and an echocardiogram revealed a patent ductus arteriosus, which

is a common life threatening condition causing hypotension. The treatment involves risky medication therapies like Indomethacin. For events 2-4, although physicians would prefer updating parents directly, having more detailed information available for the parents to review after being updated is important in the education process. Complex conditions such as apnea, anemia and jaundice could be signs of either life threatening problems such as intraventicular hemorrhages and biliary atresia, but more often are part of the normal stages of development that require patience and time. Preparing parents to expect these non-emergency, anticipated conditions ahead of time will reduce anxiety and build trust.. Educated parents tend to feel less vulnerable, more empowered and engaged [14].

The overall background of stress during this period is riddled with episodic roller-coaster moments of relief and worry that is dictated by the clinical picture. Most communicated information during this period falls into one of three categories: (1) diagnosis and prognosis (events 1,7,8), (2) policies and procedures (events 2,5), and (3) routine care (events 6,7). The timing of information delivery is important to patient treatment and parental care. Early awareness of important test results such as the presence of a hemodynamically significant Patent Ductus Arteriosus can expedite communication between HCP and parents so that time sensitive treatments can begin sooner (event 2). Our software would enable this function by sending a text message to the HCP as soon as the result appears in the EHR.

Discharge. The discharge period is one of the happiest yet intimidating times, marking the beginning of a new phase in TJ's care in the hands of his parents. Proper parental education is more important now than ever to TJ's well-being. Unfortunately, the discharge meeting has similar time and content constraints as the initial one that occurred nearly 2 months earlier. Researchers show that parents who have been educated all along about their infant's clinical issues, as our system would permit, are more prepared to take over as the baby's primary caregiver [15,16]. Following the same delivery strategy, the HCP will typically give TJ's parents an overview – this time of his special needs at home. The HCP will introduce issues that were not relevant to his hospital stay but important in the 'outside world' such as TJ's vulnerability to respiratory synctius virus infections and associated complications - therefore the need for medication prophylaxis. Proper parental education and understanding of TJ's developmental needs (i.e. sensory stimulation, engagement) at home would maximize his potential for a normal life – the discharge meeting only begins the education. Our system will supplement the issues discussed with additional information that the parents can review, so they can better learn from their pediatrician and TJ's development care team.

Proposed system design and functionalities:

Figure 1 illustrates the major components of our proposed system. A knowledge repository consists of reliable information to be delivered to parents/guardians and healthcare providers; a personalized parent-patient (PPP) model matching neonate events from the patients' electronic health records to parental roles and their information needs; an algorithm that personalizes the information delivered to parents/guardians; and a notification component for informing the appropriate parties when new information becomes available or previously delivered information is updated.

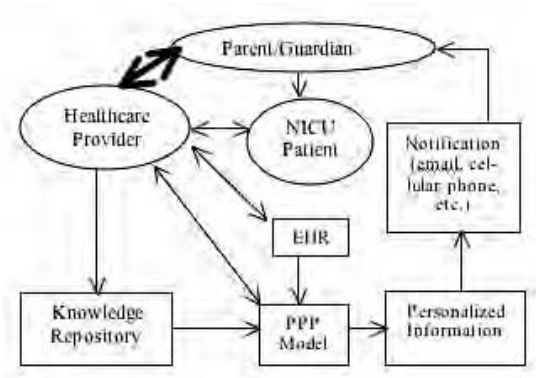

Figure 1: System Design

The knowledge repository (KR) stores all documents to be delivered and are approved by a staff member, which are reviewed and reapproved subsequently. Entering a document to the KR restarts the personalization algorithm to compute a relevance score of a new document for each PPP model. The document is marked for delivery for each PPP model for which the document's relevance score exceeds the threshold. A healthcare provider is then notified that new information is available for delivery, and on approval, the parent/guardian is notified that they can access it. The PPP model takes EHR data and maps it through its meta-data schema to categories of information delivery. Updates to an EHR will trigger the personalization algorithm to re-compute the relevance score for each document in the KR. After this is completed, the articles are recommended, approved, and delivered to the parents/guardians and/or healthcare providers associated with the appropriate child's record.

The relevance score for each document is based on weights developed by neonatologists and NICU staff based on how each document is triggered by the context of a neonate event, and answers a typical patient-parent information problem. Personalization comes from model matching the metadata of specific relevant documents to the metadata from the PPP models. If both a document and a PPP model contain the same term in their metadata, then the relevance score of the document increases by its weight (representing the informative urgency of the information for the PP context). If the document contains too many keywords not found in the PPP model, then the document's relevance score decreases by an "unlikely information" weight. Otherwise the score is left unchanged. After each document has been assigned a relevance score for each PPP model, those documents with relevance scores above a certain threshold will be queued

for approval for delivery to parents/guardians. The initial prototype is implemented with this procedure. We are currently experimenting with more sophisticated personalization algorithms to help improve the accuracy of the relevance score for a set of representative neonate scenarios (including TJ's), while reducing the burden on the HCP reviewers and approvers by summarizing displays and clusters of indices to the (as yet few, brief, and to-the-point) references. This raises many issues of informatics research we briefly address in the concluding section.

Table 2 shows how the system can improve communication between the parent and TJ's HCP. As the details of each event are recorded in the EHR, the metadata associated with each entry is compared with the metadata of the knowledge resources according to the personalization algorithm. The knowledge resources matching the EHR are queued for delivery to TJ's parents. The HCP may also choose to manually deliver certain documents from the KR. Messages are sent by cell phone to the parents immediately after the documents are approved. In some cases, the physician may not be aware of relevant updates to the EHR and the system will alert the physician of this, increasing communication efficiency. We now give an example of how the system can be used to deliver information to TJ's parents.

Table 2: Knowledge Resources for Clinical Scenario

	Knowledge Resource		**SMS Messaging**	
Event (#)	**Automatic (EHR guided)**	**Manual**	**To MD**	**To Parent**
1	NICU orientation, Prematurity, sepsis, Hepatitis prophylaxis, RDS, CPAP, CBC, CRP	Apgars, Group B Streptococcus, Blood transfusions	X	X
2	Intubation, Surfactant			X
3	Echocardiogram			X
4	PDA, Indomethacin		X	X
5	Extubation, CPAP			X
6	Store breastmilk, NGT			
7	Jaundice, Phototherapy, apnea, Caffeine	Kangaroo care		X
8	Transfusion			
9	Discharge instructions			

Discussion and conclusion:

We outline an informatics system that augments personal communications between parents and health care providers (HCPs), so that the information they "pull" from many sources can be channeled and interpreted in the context of their child's problems. The personalized technology of the "push" system will allow pertinent information to reach parents, and address their child's clinical status, in the most time sensitive manner. As we discussed, early and continuous education of parents has proven to be very effective in a NICU setting. In TJ's case, early presentation to the parents of a commonly anticipated clinical scenario during the NICU orientation, such as the likelihood of blood transfusion, will address several issues. It will allow TJ's parents time to assimilate and ask about the need for such a procedure, raising issues about TJ's safety and comfort, and the safety of the blood supply [17]. By presenting all of the information to TJ's parents as early in the process as possible, it will also allow the family time to find donors, and have them screened, for a directed blood donation, if that is something they want. Blood transfusions require parental consent. Having addressed all such relevant concerns earlier during TJ's course of treatment will allow the HCPs to care for TJ, and his family, in the most efficient way possible.

In a situation of greater emergency, such as TJ's need for intubation, the "push" system is also an effective tool to alert parents to the fact that their child's clinical status has changed. While we would not advise alerting parents of intubation via the system, it does provide the HCP with the opportunity to reach the parents and let them know that they need to call the unit to speak with their attending physician as quickly as possible. The system will also allow parents to be pushed information regarding the reasons for TJ's intubation, and the potential side effects of long term oxygen use. While we would not expect parents rushing to their child's bedside in an emergency situation to stop and read the information provided, it is reasonable to assume that they would have questions regarding the above issues. The "push" system will allow the HCP to anticipate common concerns of parents in this situation, and to address those concerns as quickly as possible. By sending the information to the parents electronically, the parents will be able to read and digest the information, and its implications, when they are ready. In this format the parents will also be able to revisit the information as often as needed, until they are comfortable with their own understanding of TJ's situation.

Currently, HCPs and administrators are the main users of EHRs. This proposal suggests leveraging the EHR as part of a personalized educational tool that uses physicians to direct the pushing of relevant educational knowledge to NICU parents. The implementation challenges involve (1) validation of knowledge resources, (2) appropriate mapping of KR to EHR content via the PPP model, (3) HIPPA and security, (4) integration into the already overtaxed physician workflow, (5) parental literacy, and (6) implement integration with EHR and other legacy systems. Our system will integrate into everyday workflow with mini-

mal perturbation of existing workflow by sending information to patients "on the fly" as they are entering orders, notes, or updating problem lists.

There are many informatics challenges in developing the system we have outlined here for the NICU. The personalization of information over multimedia databases can involve multiple steps of extracting reference literature, summarizing it, and matching it to a query based on contexts of extraction mapped to clinical databases, as investigated and carried out in the PERSIVAL project over a considerable period of time [18]. Many issues of text mining, semantic information modeling and query definition and refinement are involved in ways that present considerable challenges for a full-fledged system design. We have outlined a scenario in the NICU which, with others, are serving our group as use cases in the design of a prototype system for NICU-specific customization of information [19] in a patient-centered manner [20], but that will address issues unique to this health care context, where parents and guardians are the ones being communicated with, and where often inter-cultural and language issues must also be addressed [21]. The present paper summarizes some of the NICU specific factors that make this project such an important health informatics challenge to address.

Abstract

A computer-based learning system called Electronic Patient Record (EPR) Laboratory has been developed for students to acquire knowledge and practical skills of EPR systems. The Laboratory is basically for self-learning. Among the subjects dealt with in the system is health information ethics. We consider this to be of the utmost importance for personnel involved in patient information handling. The variety of material on the subject has led to a problem in dealing with it in a methodical manner. In this paper, we present a conceptual model of health information ethics developed using UML to represent the semantics and the knowledge of the domain. Based on the model, we could represent the scope of health information ethics, give structure to the learning materials, and build a control mechanism for a test, fail and review cycle. We consider that the approach is applicable to other domains.

Keywords:

learning support system, health information ethics
conceptual model, UML, electronic patient record system

Introduction

In recent years, the introduction of electronic patient record (EPR) systems into hospitals has influenced the roles and responsibilities of personnel in charge of patient records significantly. At the Department of Health Informatics, Kawasaki University of Medical Welfare, we have about 80 student enrollments each year, and about a half of them aim to work for hospitals as patient record administrators or as health care information technologists in charge of health information systems. To assist students to prepare for EPR systems, we have been developing a computer-based learning system called Electronic Patient Record (EPR) Laboratory for over five years. The details about the EPR Laboratory are discussed in our previous paper (in Japanese) [1]. The system is designed to supplement conventional lectures on health information systems given as part of our undergraduate curriculum based on Recommendations on Health Informatics Education, 2001 by IMIA WG1. Using the Laboratory, the students learn the fundamentals of EPR systems including operational aspects and the subjects connected with patient information handling. It is basically meant for self-learning. When a student failed a test, the system shows which questions were not answered correctly. Then student must review the materials and try the test again. We call this a test, fail and review cycle.

Among the subjects dealt with in the EPR Laboratory is health information ethics. We consider it to be of the utmost importance for personnel involved in patient information handling. Although recently some textbooks on the subject have become available [2-4], health information ethics is still very new, relevant guidelines are updated or published yearly, and the domain is changing and evolving rapidly. There is a variety of material on a range of topics. The materials and tests were arranged sequentially in the Laboratory; however, topics are not necessarily sequentially ordered, and a sequential order is not appropriate for such a complex subject as health information ethics. It was harder to capture and represent the domain than in conventional subjects. Further, when a student failed a test, it was not necessarily possible to indicate automatically which part or all of materials that should be reviewed.

To overcome the problems, we developed a conceptual model of health information ethics using UML. The objectives were to represent the domain of health information ethics, to give structure to learning materials including documents (descriptive texts, published guidelines), exercises and tests, and to build a control mechanism for a test, fail and review cycle into the Laboratory. The definition of health information ethics itself is beyond the scope of the present study, since there is no commonly agreed definition. Instead, we present the developed conceptual model, describe how it is applied in the EPR Laboratory, and discuss the usefulness of the approach.

Materials and methods

Electronic patient record (EPR) laboratory

The present study makes use of the EPR Laboratory as a working bench. The EPR Laboratory was developed using Cache 5.0.11 (InterSystems). It is used in our Health Data Management Practice course for the third year students and delivered in a computer room with one we b server and 140 client PCs. The system is used only for educational purposes

and is not a full-fledged EPR system. The system is designed mainly 1for the students to learn the fundamentals of EPR systems through practices, and 2for instructors to prepare learning materials. EPR Laboratory aims to support the students to learn not only operational aspects but also healthcare services delivery and underlining information technology (IT). IT topics such as information security are covered in the EPR Laboratory in order that the students understand why they should acquire IT knowledge to deal with patient information. Details of IT topics such as SQL and XML are covered by other courses.

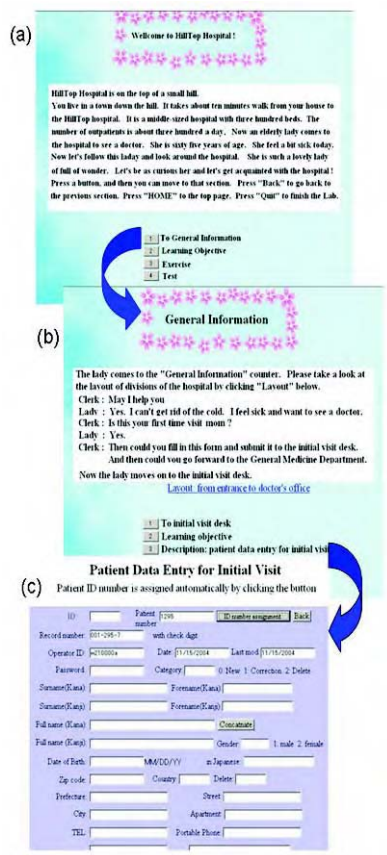

Figure 1 - EPR Labatory: a) The introductory section; b) Description about general information; c) Data entry for patient basic data

Learning materials are arranged in sections, and in each section, an objective(s), descriptive texts and exercises are given. Figure 1 shows the screens of the introductory section on the organization and functions of a hospital and patient flow. English messages in Figure 1 are prepared only for this paper, and in the actual system, all messages are shown in Japanese. The section starts with a fictitious story that an elderly lady comes to visit a hospital (Figure 1(a)). The descriptions continue as the lady moves from general information, initial visit desk, doctor's office, and so on. Figure 1(b) is the screen of general information. Figure 1(c) is the screen of the basic patient data entry, where the students practice operations. There are only two levels of access mode: the record administrator mode and the doctor mode. In the former mode, only limited operations are available including basic data entry, creation and registration of templates for data entry, semi-automatic coding of diagnoses (ICD-10), computation of hospital statistics, and so on. At certain point, there is a test, and the students may not move on to the next screen until they pass the test.

To assist instructors, facilities for preparing teaching materials and tests are provided. Questions on a test may be designed and edited using a textbox, check box, list box and so on, and the score for each question and the pass criteria of the test may be specified.

Conceptual modeling with UML

Modeling is a proven and well-accepted engineering technique in software engineering and it has been applied in a variety of health informatics studies [5-9]. In our study, a conceptual model was developed to solve the problems encountered during the development of the learning contents of health information ethics.

Results

We consider health information ethics a subject that everyone who has access to information systems with patient data should learn. Two levels of learning objectives may be distinguished: the first level for general users of health information systems, and the second level for those who are responsible for patient information handling. In the following, we will focus on the learning objectives of the second level; that is, the objectives for students who aim to be health information professionals.

A conceptual model of health information ethics

General outline of the model

Health information ethics covers both health care services (patient care) and medical and health research. The domain includes a wide range of topics and there are various types of relations among the topics. To represent the knowledge of the domain of health information ethics, we adopted the information modeling technique and developed a conceptual model using UML [10].Figure 2 shows the representation of a simplified version of the model. The model represents the scope of health information ethics covered in our current course including health ethics, information ethics, information security, EBM, and ethics for health information professionals. The conceptual model was developed to give structure to learning materials and to build a control mechanism into the test, fail and review cycle in the EPR Laboratory.

Terms and concepts

The model consists of classes and relationships among the classes. A class, rendered as a rectangle in UML, is used to model abstractions that are drawn from the domain health information ethics. In Figure 2, HealthInf and HealthEthics are examples of classes. We use a short name for a class because of space limitations. HealthInf, for example, is

short for health information. Each of the classes (abstractions) is a part of the vocabulary of the domain.

There are three kinds of relationships: dependencies, generalizations and associations. A 'dependency' is used to show one thing using another. It is rendered as a dashed line directed to the thing being depended on. In Figure 2, for example, there is a dependency from the class 'EBM' to the package 'Epidemiology', where a package (rendered as a tabbed folder) is the basic grouping with which we may organize a model. We use a package when the contents are relevant but are broad in scope and are taught outside the course. 'EBM' uses the basics of the subject 'Epidemiology' taught elsewhere. In software, a 'dependency' means a change in specification of one thing may affect another thing that uses it.

A 'generalization' is a relationship between a general thing (called the parent) and a more specific kind of that thing (the child). It is rendered as a solid line with a large open arrowhead pointing to the parent. In Figure 2, the class ClinicalInf (short for clinical information) is a child of HealthInf. A child inherits the properties of its parents, and it may also have its own properties in addition to those found in its parents. A class may have zero, one or more parents. A class that has no children is called a leaf class.

An 'association', rendered as a solid line connecting classes, is used to show structural relationships; that is, objects (to be described later) of one thing are connected to objects of another. An 'aggregation' is a special kind of association and is used to model a whole/part relationship. It is shown with a diamond at the end. For example, SecurityPolicy is a part of InfSecurity (Information Security) in Figure 2.

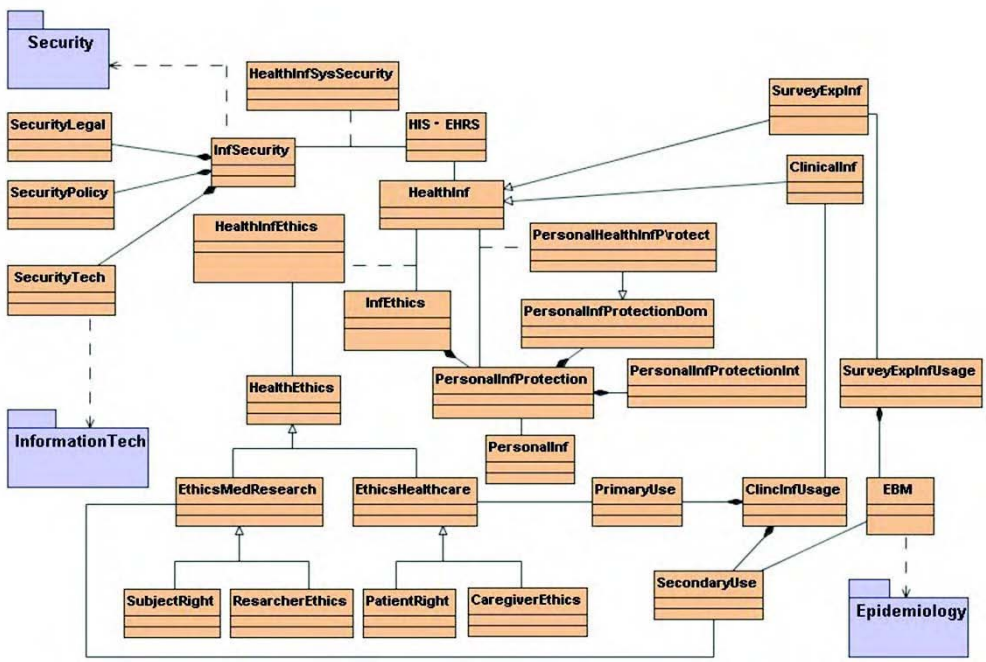

Figure 2 - A conceptual model of "Health Informatin Ethics" (simplified version)

Conceptual model in EPR laboratory

The conceptual model has been incorporated into the EPR Laboratory. Some of the implementation details are described below.

Objects in EPR laboratory

In our application, teaching materials (including documents, descriptive texts, exercises and tests) are physical things and are considered objects. Each object belongs to a class, and a class is a description of a set of objects that share the same attributes, relationships and semantics. There are also abstract classes (classes with no objects). Classes with objects may explicitly be called concrete classes. In our application, concrete classes are mostly leaf classes. In Figure 2, leaf classes are omitted because of space limitations. Below in ResearcherEthics for example, there are classes ResearcherEthicsGuideline, ResearcherEthicsText and ResearcherEthicsTest. The objects that belong to the class ResearcherEthicsGuideline are the guidelines including World Medical Association Declaration of Helsinki Ethical Principles for Medical Research Involving Human Subjects, and the important ethical guidelines on medical or epidemiological research published in Japan. There are dependency relations among the classes, e.g., from ResearcherEthicsTest to ResearcherEthicsText. This means some of the texts are used or referenced by a test, and changes in the texts may affect the test but not the reverse.

Attributes of classes in EPR laboratory

For concrete classes with learning materials as objects, the following attributes are defined, where attribute names are shown in italics. The attributes may be considered as metadata of learning materials. The materials may be documents (such as guidelines), tests and so on.

Class_name

a) title : the title of the material

b) description : the description of the material

c) responsible_entity : responsible entity for the material

d) year_month : year (and month) of publication or writing

e) depend_on : the title(s) of the material(s) that this material depends on

For a test, the following attributes are defined in addition to those defined in a) through e) above:

f) question_ids : identifications of the questions belonging to this test

g) pass_criteria : the pass criteria for this test

An example pass criteria for a test may be 'the sum of all questions is greater than 80 and Question 1 is greater than 5 and Question 7 is greater than 5'.

For a question comprising a given test, the following attributes are defined in addition to the attributes a) to e) above:

f) answer : answer(s) to this question

g) scoring_method : the method for scoring this question

Control of test-fail-review cycle

There are three levels of questions: fundamental, advanced, and applied. A fundamental question is such that an answer can be found easily in a learning material. A question is advanced if the answer may be obtained from multiple materials. A question is applied if an answer cannot be found directly from materials.

If a student fails in answering fundamental or advanced questions, they are guided to read the relevant materials that are indicated by the '*depend_on'* attribute. As an example, Figure 3 shows a fundamental question on personal data protection. The question is stored as an object of the class representing questions for the topic with the following attribute values:

a) title : question 1

b) description : Check if a student has an understanding of the outline of the OECD eight principles

c) responsible_entity : name of the composer of the question

d) year_month : 2005 Dec

e) depend_on : ResearcherEthicsGuideline. 'OECD Guidelines on the Protection of Privacy and Transborder Flows of Personal Data'

f) answers : 1. e 2. b 3. a 4. g

g) scoring_method: type 3

The value of the attribute '*depend_on'* shows the material(s) that this question is dependent on; that is, the title of the guideline preceded by the class name. The guideline itself is stored as an object of the class 'ResearcherEthicsGuideline', with the following values of the attributes (shown only partly):

a) title : OECD Guidelines on the Protection of Privacy and Transborder Flows of Personal Data

b) description : ……

For fundamental and advanced questions, answers are selected from a list of choices and the scores are computed automatically according to the rules specified by the attribute '*scoring_method'*.

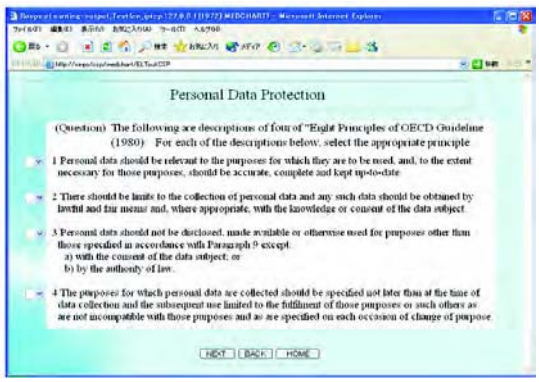

Figure 3 - A sample fundamental question on 'personal data protection'

Applied questions are given toward the end of the course. The questions are often taken from the real life problems that could be very complex. For this type of question, a student is asked to answer in writing in a textbox. The answer is sent to the instructor, and the instructor gives a score. A sample applied question is shown below.

A sample applied question:

> Assume that there was a large-scale accident, and a number of injured people, unconscious and unidentified, were carried into your hospital. Then you receive a phone call from a person saying that his relative might have been involved in the accident. He would like to know whether the named person is among the injured people brought into your hospital. Is it appropriate for you to answer his question over the phone? Discuss why you consider appropriate or not appropriate.
>
> 1. appropriate 2. not appropriate

The applied questions on personal data protection are taken from Q & A for The Guideline on Healthcare and Welfare Entities Handling of Personal Information issued by the Japanese Ministry of Health, Labour and Welfare.

Discussion and conclusion

The EPR Laboratory has been developed for over five years to assist students to prepare for Electronic Patient Record (EPR) systems. The system is meant to supplement conventional lectures. Among the subjects covered in the EPR Laboratory, is health information ethics. For a newly emerging concept such as health information ethics, it was necessary to have a method to represent the knowledge of the domain and organize learning materials in a systematic way. Further, it was also necessary to build a mechanism to tell the students about their weak points when they failed a test so they could review materials more appropriately.

A conceptual model of health information ethics was developed to organize the contents of health information ethics in a way that expresses the semantics of the domain more visibly. Modeling is a proven and well-accepted engineering technique in software engineering, and many aspects of modeling techniques for software apply to our application as well.

The contents of health information ethics in the EPR Laboratory are intended to educate students who aim to be health information professionals. We consider that ability for making decision on real problems of health information ethics may only be acquired through practice in health care settings but, at the same time, we consider students should acquire the fundamental principles before they are involved in the real-life decision-making. The Laboratory may also be used to educate students aiming for to be health care professionals, or for training of health care professionals.

Incorporation of the model into the EPR Laboratory provides a template for storing learning materials in an orderly way, and builds a control mechanism for a test, fail and review cycle. It also provides a means to thoroughly examine the necessity and suitability of the contents. We consider that the approach is applicable to other domains.

Abstract

The purpose of this case study is to describe three incremental personal digital PDA-based informatics strategies aimed at improving screening for tobacco use and guideline-based tobacco cessation management: 1) PDA clinical log with tobacco cessation diagnoses and plan of care options, 2) PDA decision support system, and 3) PDA decision support system with infobuttons - context-specific links to the National Cancer Institute's Cancer Information Services tobacco cessation information. These strategies were implemented within the context of an evidence-based advanced practice nurse curriculum at the Columbia University School of Nursing.

Keywords:

tobacco cessation, decision support, nursing informatics

Introduction

Tobacco use is a significant global issue. Cigarette smoking is the leading cause of lung cancer and mortality related to lung cancer and has been implicated in other cancers such as larynx, oral cavity and pharynx, esophagus, bladder, stomach, pancreatic, liver, renal cell and renal pelvis, cervix, and acute myeloid leukemia [1, 2]. Tobacco use contributes to 430,000 deaths per year in the U.S., which according to Healthy People 2010 represents 5 million years of potential life lost [3]. Healthy People 2010 further reports that fifty billion dollars per year of direct medical costs are a result of cigarette smoking. In the U.S. as in other countries, the goal of reducing tobacco use remains an urgent necessity for improving both quality and length of life. Meeting Healthy People 2010 goals related to tobacco cessation is estimated to prevent an addition 7.1 million premature deaths [2].

The purpose of this case study is to describe three incremental personal digital PDA-based informatics strategies aimed at improving screening for tobacco use and guideline-based tobacco cessation management: 1) PDA clinical log with tobacco cessation diagnoses and plan of care options, 2) PDA decision support system, and 3) PDA decision support system with infobuttons - context-specific links to the National Cancer Institute's Cancer Information Services tobacco cessation information. We also provide descriptive data regarding use of the first and second strategies.

These strategies were implemented within the context of an evidence-based advanced practice nurse (APN) curriculum at the Columbia University School of Nursing. The first strategy was developed to serve as a control for the second strategy in a randomized controlled trial that is currently in progress. The third strategy is in the design phase for a second randomized controlled trial.

Tobacco cessation and nursing practice

Although tobacco use prevention and smoking cessation counseling are within the purview of nursing practice, actual or perceived barriers frequently deter nurses from undertaking such interventions. McCarty et al. reported reasons given by nurses for not advising patients about smoking cessation: lack of a nursing time, lack of knowledge related counseling techniques, and reluctance to ask a patient to give up a coping mechanism during a hospitalization were given as reasons for nurses not to advise patients about smoking cessation [4]. They also found that nurses often felt counseling was ineffective. Current smokers in this study group were less likely to give smoking cessation advice. In another study, McCarty et al. found that only 50% of patients identified as smokers received smoking cessation advice [5]. Similarly, Gomm et al. reported nurses' attitudinal barriers of 'not my place', 'they'll quit if they want to', and not wanting to add to the patient's 'stress' [6]. In a study of pregnant women, midwifery assessment of smoking status and providing advice to pregnant women was accepted as part of the routine care [7]. Further, the women in the study didn't believe that assessing smoking status or providing advice altered the relationship between them and their midwife. Therefore, the nurse's perception may not be aligned with the perception of the patient about smoking cessation advice.

According to the U.S. Surgeon General's report [8], approximately 36 million American smokers will have at

least one outpatient visit each year but only about half of these smokers will receive smoking cessation advice at their visit. This is consistent with data from the Robert Wood Johnson Foundation that suggests that almost all obstetricians report asking about tobacco use in pregnancy, but fewer than half go on to discuss cessation strategies and offer self-help materials [9]. Smoking cessation advice and treatment is within the purview of the APN. Consequently it is important to design strategies that support guideline-based care and to integrate these into the curriculum so that APN students can address this important health concern during and after their clinical training.

Decision support and guideline-based care

For more than two decades computers have assisted in the provision of reminders to clinicians regarding standardized protocols or guidelines [10-12]. A number of RCTs have demonstrated that computer-based reminders decrease errors of omission [10, 13, 14] and increase compliance with preventive care guidelines [15, 16]. Several recent systematic reviews also suggest that such systems impact clinician adherence to guidelines [17-19].

Additional studies support the potential for decision support to affect clinician behavior related to smoking cessation. A study of physicians in Vermont revealed that even though they were familiar with the U.S. Public Health Service guideline [8] on tobacco use and tobacco dependent treatment and had positive attitudes toward it, they were unfamiliar with smoking cessation resources [20]. The authors concluded that interventions to improve clinician adherence to the guideline should address the inaccurate perception that smokers are unreceptive to counseling and increase knowledge of smoking cessation resources and that a decision support system could meet these needs. An randomized controlled trial of a multifaceted intervention that included computer-generated prompts for care provision by clinic staff found that patients in the experimental group were more likely to report receiving smoking cessation advice by nursing and anesthesia staff and to receive nicotine replacement if nicotine dependent [21].

PDA clinical log at the Columbia Univ. School of Nursing

The PDA clinical log has been in use for more than four years and was designed to serve multiple purposes. These include: student documentation of clinical encounters using standardized nursing terminology and other health-care-related coding systems; use of benchmarking reports to learn to critically examine one's practice over time; and faculty monitoring of student performance. Key steps that were required to create a system that supported these multiple purposes were: design of the system architecture, selection of data elements and standardized terminologies for the data elements, design and implementation of the user interface, design and implementation of the database and knowledge base, and design and implementation of reports. These details have been described in detail elsewhere [22, 23].

APN students enter data using Palm OS devices and synchronize with a central database through Ethernet cradles, WiFi, Internet, or cellular network depending upon their location and type of device (e.g., Palm TX, Treo 700). Faculty and student reports are generated every two weeks.

Use of the PDA Clinical Log is a required part of the APN clinical curriculum. APN student participation in the randomized controlled trial that is testing the affect of a PDA support system on clinical care processes is optional.

Infobuttons and infobutton manager

Infobuttons are context-specific links between a clinical information system and web-based information resources that attempt to anticipate users' information needs and to automatically satisfy those needs [24-27]. Infobuttons are built upon three premises: high-quality, web-based resources exist and are continuously updated by their developers; clinical information systems should access existing web-based information resources, rather than develop and maintain content; and context-specific links within clinical information systems can provide more efficient access to web-based information resources. Infobuttons are currently deployed within two clinical information systems at Columbia University Medical Center: WebCIS and Eclipsys, as well as at two other institutions. In addition, they are accessible via the PDA in an experimental system called PalmCIS [28]. Cimino has recently described the use and positive influence of infobuttons on clinical care [29].

Materials and methods

PDA clinical log with tobacco cessation diagnoses and plan of care options

To create an appropriate application to serve as the control for the PDA decision support system, we needed to make sure it was possible to document all aspects of guideline-based care, i.e., the diagnosis of tobacco dependence and the associated plan of care items for Diagnostics, Procedures, Prescriptions, Patient Teaching and Counselling, and Referrals. First, the U.S. Public Health Service guideline was decomposed into its constituent elements by an expert in tobacco cessation and then reviewed by an additional expert in tobacco cessation and an expert in guideline representation [30]. Then, we represented the diagnostic and intervention concepts with codes from existing terminologies or created new codes in instances where existing terminologies were insufficient to represent the concepts. Next, the guideline-related terms were then organized into existing lists of terms in the menus for diagnoses and the five categories in the plan of care.

PDA decision support system

The PDA decision support system for tobacco screening and smoking cessation management provides decision support for a short clinical intervention based upon the Ask, Advise, Asses, Assess, and Arrange smoking cessation model [8, 30, 31]. As shown in Figure 1, there are two

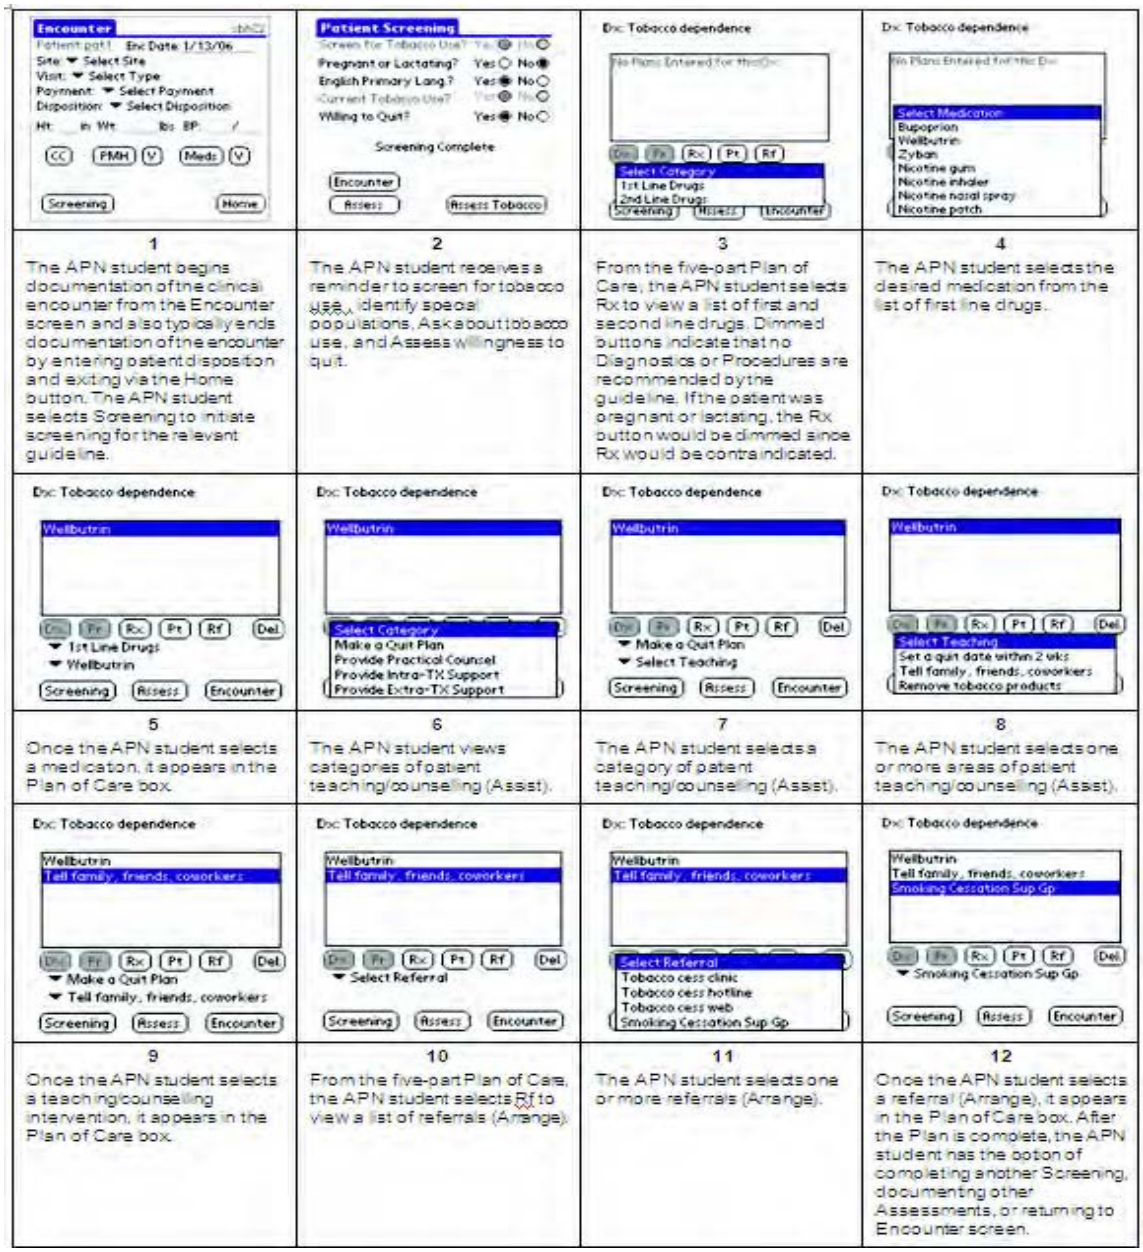

Figure 1 - PDA decision support system for tobacco cessation

aspects to the decision support: the student is prompted to screen and is presented with a guideline-based documentaion template for a plan of care that is tailored according to the smoker's willingness to quit and whether or not they are pregnant or lactating.

PDA decision support system with Infobuttons

Infobuttons are enabled though an Infobutton Manager, which provides a standardized interface for matching user contexts to information resources. This is done through six different methods for accessing the information resources: simple link, concept-based link, simple search, concept-based search, intelligent agent, and calculator [24].

For the PDA decision support system with infobuttons, our design is based upon the use of simple links and concept-based links to access the National Cancer Institute's Cancer Information Service tobacco cessation information within the Patient Teaching and Counselling and Referrals sections of the guideline-based document template. For example, if an APN student wishes to access patient edu-

cation materials in Spanish about making a Quit Plan, she will select the infobutton associated with that intervention and through cellular telephone technology access the Cancer Information Service resource of relevance.

Because the Cancer Information Service resources are not designed to optimize viewing on small devices such as PDAs and cellular telephones, we must also develop and implement an approach for displaying this information in a manner suitable for these small devices.

Results

Descriptive data are reported for Fall semester 2005 (PDA clinical log with tobacco cessation diagnoses and plan of care options) and for Fall 2006 (PDA decision support system) so that they reflect similar points in the APN curriculum. The third strategy is still in the design phase.

PDA clinical log with tobacco cessation diagnoses and plan of care options

In Fall of 2005 when all APN students received the PDA clinical log that included tobacco cessation diagnoses and plan of care options, 1132 encounters were documented using the PDA clinical log for persons more than 9 years old. Only one encounter included a tobacco dependence diagnosis. The associated plan of care included teaching and counselling related to “Make a Quit Plan”.

PDA decision support system

In Fall of 2006, 13 students randomized to received decision support for tobacco cessation entered 150 encounters in which they received a reminder to screen. Patients were screened in 64% (n=96) of the encounters with reminders. Fifteen of the 96 screened were identified as current smokers and 8 indicated that they were willing to quit. However, only one tobacco-related plan of care was documented in the guideline-based documentation template.

The majority of those screened were female (75%) and either Hispanic (42%) or Black (27%). Forty-four percent were between 19-35 years of age. Of those screened, 30% were pregnant or lactating and 42% did not speak English as their primary language. Among those identified as currently smoking, 33% were pregnant or lactating and 73% did not speak English as their primary language.

Discussion

The screening rate for those APN students who received the PDA decision support reminder to screen could be viewed as encouraging, but this only resulted in an associated plan of care in one of eight patients identified as willing to quit smoking. Further study is needed to determine if this is an artifact of the documentation process or an actual quality of care issue. Infobuttons have the potential to provide additional decision support through provision of access to Cancer Information Service resources. The effect of the PDA decision support system on screening rates and adherence to guideline recommendations is currently being tested in a randomized controlled trial in which the control groups receive PDA decision support for either depression or obesity management. A second randomized controlled trial will compare the PDA decision support system and the PDA decision support system with infobuttons on use of Cancer Information Service resources by APN students and the patients they refer to the resources.

Conclusion

There has been little work focused on decision support for APN practice or specifically for tobacco screening and smoking cessation management. Our case study describes our incremental approach to designing PDA-based informatics strategies for screening and management of tobacco dependence within the context of an evidence-based APN curriculum. It is vital that informatics methods and information technologies be conscientiously applied to address this significant health issue from both the clinician and consumer perspectives. Our hope is that by integrating these approaches into the curriculum, the benefits will affect not only the patients the nurses care for during their APN education but also the patients they will care for after graduation through application of such tools into their APN practice.

Needs Assessment for the Computer-interpretable Hypertension Guideline at Public Health Centers in Korea

EunJung Lee[a], SoYoung Kim[b], InSook Cho[c], JiHyun Kim[a], JaeHo Lee[d], Yoon Kim[b]

[a] *Center for Interoperable EHR, Korea*
[b] *Department of Health Policy and Management, Seoul National University College of Medicine, Korea*
[c] *Department of Nursing, Inha University College of Medicine, Korea*
[d] *Department of Emergency Medicine, University of Ulsan College of Medicine, Korea*

Abstract

Computer-interpretable hypertension guidelines can make for the improvement of blood pressure control rate by assisting clinicians at the point-of-service to behave according to the evidence-based guidelines. We surveyed 117 public health centers in Korea to evaluate current hypertension management status with clinicians' performance, and to analyze the needs for the computer-interpretable hypertension guidelines. Hypertension control rate was 57%, while clinicians overestimated it as 79.5%. 60.4% of patients were treated with 2 or more antihypertensive medications, and most frequently used drug class was calcium channel blocker. Inappropriate prescription rate of contraindicated patients was 2.6%. Two-thirds of clinicians agreed to implement the computer-interpretable hypertension guideline. Implementation of computer-interpretable hypertension guideline is considered as a way to improve the hypertension control rate and to reduce the inappropriateness of the therapeutic choice.

Keywords:

needs assessment, hypertension, guideline, practice guideline

Introduction

For the prevention of cardiovascular diseases, hypertension management takes important portion. Yet world-wide hypertension control rate is known to be less than one-third, especially in Korea, it is about 17%. Computer-interpretable guideline is suggested as an intervention tool for the quality improvement of patient care as modifying clinicians' behavior. This is a preliminary study for developing computer-interpretable hypertension guideline, which is designed to improve hypertension control rate in primary health care. We intended to analyze current hypertension management status, clinicians' performance and needs for the CIGs.

Materials and methods

We surveyed 117 public health centers and 154 clinicians in Gyeonggi province. We extracted medical records of hypertension patients from the centers' clinical database during a 10-month period. Data included blood pressure, medication, comorbid disease, and others. Questionnaire was answered by the clinicians to assess their adherence to hypertension guidelines and needs for the CIG program.

Results

38,474 patients' data and 41 clinicians' survey was analyzed. 61% of clinicians agreed to implement the computer-interpretable hypertension guideline. Hypertension control rate was 57%. Clinicians overestimated as 79.5% of patients had controlled blood pressure. Over 60% of patients were treated with 2 or more antihypertensive medications, and calcium channel blocker was the most frequently prescribed. Based on JNC7 report, inappropriate prescriptions, such as monotherapy for the stage hypertensive patient, beta blocker only for the diabetes patient, combination of beta blocker and non-dihydropyridine calcium channel blocker, thiazide diuretics for the gout patient, and beta blocker for the asthma patient, were 2.6% (N=1001).

Conclusion

Clinicians overestimated the proportion of their patients with controlled blood pressure. Implementation of computer-interpretable hypertension guideline is considered as a way to reduce the inappropriateness of the therapeutic

Development of a Personal Medical Recorder on a Cell Phone

Akihiro Takeuchi[a], Katsura Kobayashi[b], Noritaka Mamorita[b], Noriaki Ikeda[a]

[a] *Departments of Medical Informatics, School of Allied Health Sciences, Kitasato University, Japan*
[b] *Graduate School of Medical Sciences, Kitasato University, Japan*

Abstract

Paper medical records have effectively been used in chronic diseases without information technology. To facilitate self-control in hemodialysis and observe a patient's condition continuously, we developed a mobile phone-based personal medical recorder for patients suffering chronic renal failure. The application is based on Java2 Micro Edition and operates like a scheduler. The application stores laboratory data, such as BP, BUN, creatinine, HbA1c, etc., and other pertinent clinical comments into memory on a cell phone. The application can also customize, add or delete items (laboratory data, medications, questions, etc.). Detailed graphic displays of the data are shown. The data can also be sent to a PC with infrared communications. In a usage trial, patients were favorably receptive about this application and indicated that they wanted to continue using it.

Keywords:

cell phone, medical records, infrared transmitter

Introduction

Using a diary, a chronically ill person can gain an overview of his medical situation [1]. Although patients with chronic renal failure can maintain an adequate daily nutritional intake, they might also be able to recognize their own pathophysiological state and be aware of the settings for their own hemodialysis. Although data collection was more reliable with a palmtop computer than with paper diaries [2], there have been no reports presenting a PDA/cell phone-based clinical recorder for chronic hemodialysis other than for dietary monitoring [3]. Therefore, we developed a cell phone-based medical recorder for the self-management of chronic diseases.

Materials and methods

An application was designed as a self-controllable tool for chronic diseases. It consists of a calendar canvas, dataentry canvas, plot canvas, memory control module and an infrared module (Figure 1, left). The plot canvas shows graphs of clinical and laboratory data, such as BP, BUN, creatinine, HbA1c, etc. These data are stored in text form in the memory of a cell phone (maximum 200 kB). The data size of this schedule is estimated to be about 100 bytes. The monthly or daily data are sent to a PC by an infrared module.

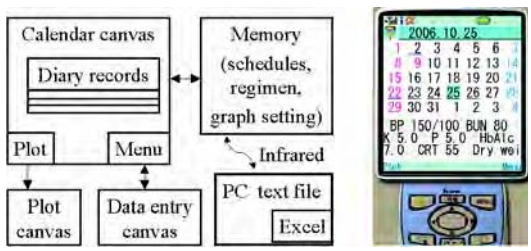

Figure 1 – Overview of the application and a calendar canvas

Results

The application was based on Java2 Micro Edition and i-Appli Tool (NTT DoCoMo, Inc.). The application (medData.jar 100 kB) operates like a scheduler. (Figure 1, right). All of the data, BP, laboratory data, medications, etc. on each day are listed on the data entry canvas. The patient interactively and personally types in numeric data and/or comments. Detailed graphic displays of data are shown sequentially on a plot canvas in years, months, weeks, or days. Color and scale customization of the plot canvas is possible for each set of laboratory data. Customizing items (laboratory data, medications, questions, etc.) is done on the data entry canvas. The application was adapted for several patients to use at the same time in one trial. The patients were favorably receptive about this application and said that they would like to continue using it. This personal medical recorder based on a cell phone could be useful as a self-management tool for patients with chronic diseases.

Implementing and Evaluating a Laboratory Information System to Optimize the Treatment of Tuberculosis Patients in Peru

Joaquin A. Blaya[a,b], Sonya S. Shin[b,c], Martin JA Yagui[d], Luis Asencios[d], Javier Vargas[d], Carmen Suares[e], Gloria Yale[f], Hamish SF Fraser[b,c]

[a] *Harvard-MIT Division of Health Sciences & Technology, USA,* [b] *Partners In Health, USA,* [c] *Division of Social Medicine &Health Inequalities, Brigham & Women's Hospital, USA,* [d]*Instituto Nacional de Salud, Perú,* [e]*Dirección de Salud IV Lima Este, Perú,* [f]*Dirección de Salud V Lima Ciudad, Perú*

Abstract and objective

Multi-drug resistant tuberculosis patients in resource-poor settings experience large delays in starting appropriate treatment and may not be monitored appropriately due to an overburdened health care system, communication delays, and missing or error-prone data. A web-based laboratory information system "e-Chasqui" has been implemented in Peru to alleviate these problems by improving the timeliness and quality of laboratory data. It has been deployed in the national TB laboratory, two regional laboratories and twelve health centers. High user satisfaction and heavy use has led to e-Chasqui is being expanded to more institutions. A study is being performed to measure its impact and generalizability.

Keywords:

clinical laboratory information system, computerized; evaluation studies; developing countries

Introduction

Treatment for MDR-TB in Peru is often delayed by over three months after initial presentation.(1) These potentially dangerous delays occur because of the long test processing time, cumbersome collection and communication procedures, and loss of specimens and test results. Similar problems are prevalent in other settings including South Africa.(2). An electronic information system can improve the handling and communication of these data between institutions. Decreasing treatment delays and ensuring an appropriate drug regimen should improve outcomes and reduce transmission.

Methods

Partners In Health has developed a web-based medical record system (PIH-EMR)(3) to support the treatment of TB, with data on 15523 patients. We created a web-based laboratory information system, "e-Chasqui" to connect laboratories to health centers to reduce delays and facilitate communication and analysis. e-Chasqui includes tools to improve data quality, notify health centers of new results, alert physicians of high-risk patients and create laboratory reports. Here we report on the system's implementation, use, and preliminary results from its evaluation.

Results

e-Chasqui has been implemented in the national reference laboratory, two of five regional laboratories in Lima and twelve health centers. Since its implementation in November, 2005, 19900 smear, 21196 culture and 3076 drug sensitivity test results have been entered. In 2006 all health centers have viewed 100% of their results online. Due to user satisfaction and heavy use, public officials have asked to expand the system to 3 other laboratories and over 10 other health centers.

Conclusions

This experience demonstrates the possible benefits of implementing a web-based laboratory information system in a low resource setting. A prospective randomized evaluation is being performed to measure its impact on delays, errors, and quality of care, including time to prescribe an effective drug regimen.

Risk analysis – A Tool for IT Development and Patient Safety
A Comparative Study of Weaknesses Before and After Implementation of a Health Care System in the County Council of Ostergotland, Sweden

Annica Öhrn[a], Gunilla Eriksson[b]

[a] *Patient safety office of county council of Ostergotland, Sweden*
[b] *Laboratory medicine unit of county council of Ostergotland, Sweden*

Abstract

There is a lack of tools to secure patient safety considering information security and health care systems. Risk analysis can be used as a systematic method for identifying risks before a medical error occurs. In healthcare is this type of analysis uncommon use. An indicator for this need of systematic proactive work is the amount of adverse advents that are reported in the deviation system .In this comparative study of a health care system during 2004 and 2006, one of the results is an reduction in the numbers of risks due to technique & equipment and in the area of training & competence. This study gives an indication of that risk analysis helps the health care organisation to develop and manage routines for reducing possible risks.

Keyword:

information system, safety management, risk management/methods, medical errors, systems analysis, quality of health care

Introduction

In the county council in Ostergotland, Sweden has a supporting system for requests and laboratory reports, called LR, and been implemented during the last year and a half. A risk analysis has been performed before and after implementation and is planned to continue regulary for the coming years. The aim of this study was to perform a comparative risk analysis for a recently implemented health care system.

Methods

Risk analysis has been performed before and after the implementation of the system. Risk analysis is a systematic tool, including: process mapping, risk identification, determination of the severity and probability of each risks and action plans. The analysis has a patient safety perspective and has been performed with a trained risk analysis team including members from different roles/specialities. The risks were categorised in areas of six potential sources; technique & equipment, rules/policies/procedures, environment, training & competence, barriers and communications & information.

Results

The risk analysis shows that the total risk points are lower during 2006 for the areas technical solutions and procedures compared to the points of the same areas during 2004.

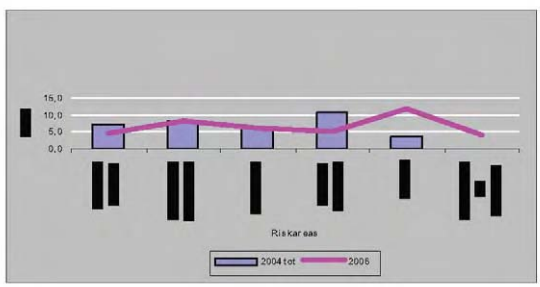

Figure 1 – Risk profile, comparison 2004-2006 LR

Discussions

The risk analysis performed demonstrated differences between the results obtained prior and after the implementation. This was especially true within the sources; technique & equipment, training & competence as well as for barriers. The risk profile within technique & equipment demonstrated that most of the risks prior to the implementation have been dealt with. Training of the personal drastically decreased the risk profile within training & competence. However, increased risks were found for the source barriers as a consequence of the introduction of new barriers, which reduced the accessibility of laboratory results. This was a consequence of the Swedish legislation for patient related information in medical records, which prevents full access of a patient's laboratory test data without the patient consent.

The risk profile for the source; rules/policies/procedures is unchanged. The numbers of risks have decreased but the risks with a high score, which were identified prior to the implementation, were never dealt with.

Conclusion

Risk analysis is a useful method for identifying and managing possible patient safety risks and also a method for proactive work in health care organisations. Systematic and regular risk analysis is preventive of managing new routines. This may be a constructive tool for the patient safety work

Multi-label Text Classification of German Language Medical Documents

Stephan Spat[a], Bruno Cadonna[a], Ivo Rakovac[a], Christian Gütl[b], Hubert Leitner[c], Günther Stark[c], Peter Beck[a]

[a] *Institute of Medical Technologies and Health Management, JOANNEUM RESEARCH Forschungsgesellschaft mbH, Graz, Austria*
[b] *Institute for Information Systems and Computer Media, Graz University of Technology, Graz, Austria*
[c] *Steiermärkische Krankenanstaltenges. m.b.H., Graz, Austria*

Abstract and objective

At nearly every patient visit, medical documents are produced and stored in a medical record, often in an unstructured form as free text. The growing amount of stored documents increases the need for effective and timely retrieval of information. We developed a multi-label text classification system to categorize free text medical documents (e.g. discharge letters, clinical findings, reports) written in German into predefined classes. A random sample of 1,500 free text medical documents was retrieved from a general hospital information system and was manually assigned to 1 to 8 categories by a domain expert. This sample was used to train and evaluate the performance of 4 classification schemes: Naïve Bayes, k-NN, SVM, and J48. Additional tests of the effect of text preprocessing were done. In our study, preprocessing improved the performance, and best results were obtained by J48 classification.

Keywords:

machine learning, classification, medical records, multi-label

Introduction

At nearly every patient contact with healthcare-providers, medical documentation is generated and stored in medical or nursing records, often as free text. With the increasing amount of stored, unstructured free text information, the need for effective and timely retrieval of relevant information is growing. In this work, we describe the development and the evaluation of an information system for multi-label classification of medical documents into predefined classes.

Methods

A random sample of 1,500 unstructured, free text documents written in German was extracted from an electronic medical record (EMR) of a general hospital in Austria. A domain expert (physician) manually classified the retrieved documents into one or more of the following classes: surgery, vascular surgery, casualty surgery, internal medicine, neurology, anesthesia and intensive care, radiology and physiotherapy. In average, 1.47 labels were assigned to a document. We built an automated multi-label text classification system in Java based on Weka [1], an open-source machine-learning framework. Four different kinds of classification schemes were compared: Naïve Bayes, k-NN, SVM and J48. 10-fold cross validation was used for evaluation. Moreover, the influence of text preprocessing (e.g. stop-word-removal, stemming, lowercasing) was studied.

Results and conclusion

Results for the F-measure [2] with and without preprocessing are shown in figure 1. J48 performed best, followed by 1-NN, SVM, and Naïve Bayes. The results were improved by text preprocessing. The best classification scheme (J48) with text preprocessing achieved an F-measure of 0.886.

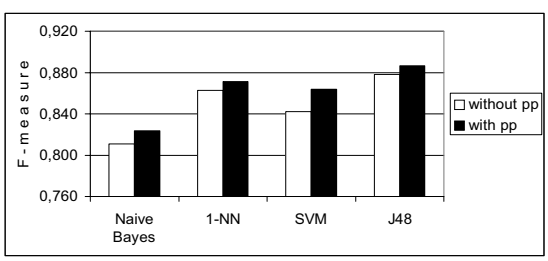

Figure 1 - F-measure with and without text preprocessing (pp)

Results show that it is possible to classify medical documents written in German originating from a general hospital with automated machine-learning classification schemes with promising results, comparable with [3]. This classification system is used in a prototype of an information retrieval system for score-calculation, thus influencing the display order of search results. Further studies are needed to evaluate the accuracy of the developed system in other hospitals as well as the user-perceived benefits of this prototype.

What Health Influences are Caused by EMR Working?- In Case of Japanese Nursing Situation

Yukie Majima [a], Yasuko Maekawa[a]

[a] *School of Nursing, Osaka Prefecture University, Osaka, Japan*

Abstract

The purpose of this study was to determine how nurses used visual display terminals (VDT) and whether the use of VDTs had any influence on their health. In our study, the use of the EMR and the health influences of introduction of the EMR were surveyed using a questionnaire in a general hospital. The results indicated that VDT works were conducted in nurse stations rather than at the bedside. Only about 10% of nurses did exercises to prevent neck, shoulder and back pain before starting work. Since more than half of the nurses remained standing while inputting, extra guidelines should be developed for this aspect as the MHLW guidelines currently only deal with seated operations. Health influences after introduction of the EMR, more than half the subjects complained of worsened symptoms including eye strain, stiff shoulders and neck, and general fatigue, all of which are signs of VDT syndrome.

Keyword:

nurses, VDT works, electronic medical record system, health influences

Introduction

Currently in Japan, the use of EMR and digital ordering systems in hospitals is increasing. Since medical service is one of the seven main fields of the e-Japan priority policy program, it is assumed that digitalization will be promoted in medical facilities. Accordingly, appropriate workplace health measures should be taken in response to changes in the working environment of nursing personnel.

Methods

1) Study period: March 8 to 29, 2005. 2) Subjects: Nursing care personnel (378 individuals) working at a private general hospital (477 beds) in Japan which had introduced an EMR around a year previously. 3) Method and contents of study: Self-reported questionnaire study. A questionnaire was delivered to the subjects and was recovered on completion under ethical cares. It consisted of questions regarding the VDT working situation of EMR((1)posture, (2)place, (3)adjust materials around PC, (4)input device, (5) time per one use of EMR, (6)brightness around PC on each shift, (7)setting-up exercise before working) and the health influences (eye strain, low vision, dried eyes, stiff neck and shoulders , numbness of fingers, back pain, fatigue, headache, stress, gloomy) after using the EMR.

Results

323 questionnaires delivered were recovered (85.4% recovery). 193 subjects (59.8%) were in their 20s, 80 (24.8%) were in their 30s, 27 (8.4%) were in their 40s and 19 (5.9%) were in their 50s. Four subjects (1.2%) did not reveal their age. The average number of years working at the hospital was 5.67.

1) The VDT working situation of EMR

VDT works were conducted in nurse stations rather than at the bedside. Since more than half of the nurses remained standing while inputting records.

2) The health influences after introduction of the EMR

Only about 10% of nurses did exercises to prevent neck, shoulder and back pain before starting work. More than half the subjects complained of worsened symptoms including eye strain, stiff shoulders and neck, and fatigue, all of which are signs of VDT syndrome (Figure 1).

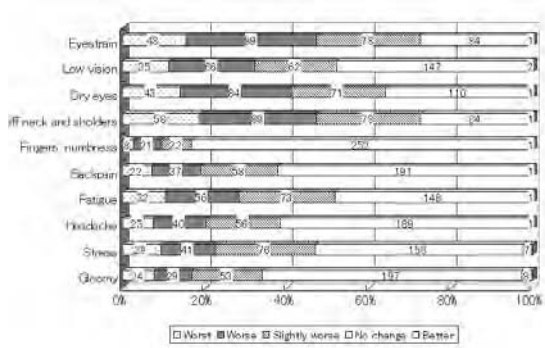

Figure 1 - Subjective signs of health influences after using EMR

Conclusion

Nurses' VDT working situations are different form those of office workers etc. Workplace health measures for VDT operations by nurses should be urgently revised based on the results of this study.

Using PDA to Transform the Long MDS-HC Evaluation Form into a Favored System

Chiao-Ling Hsu, RN, MS, Yu-Yin Kuo, RN, MS, Polun Chang, PhD

Institute of Biomedical Informatics (formerly Health Informatics and Decision Making), National Yang-Ming University, Taiwan

Abstract

The MDS-HC has been an effective home care evaluation form. However it was not yet accepted in Taiwan because it is too long for our over-burdened home care nurses. We used a self-developed PDA information representation model to design the PDA MDS-HC support system and used the Technology Acceptance Model to examine its potential acceptability. The results showed a well-designed PDA could greatly improve the usability of a originally un-favored paper system.

Keywords:

MDS, home care, PDA, information representation

Introduction

The Resident Assessment Instrument, consisting of a Minimum Data Set (MDS) evaluation form, Client Assessment Protocols (CAPs) and Triggers, has been well internationally known, applied, and even used for the insurance claim, in the long term care [1]. The MDS-HC is vary complete and covers 17 main categories and as many as 64 evaluation items. However, currently its professional completeness doesn't make it a formal evaluation form for the home care in Taiwan because it is too long for our over-burdened home care nurses.

PDA has been a potentially useful tool for mobile nursing, especially for those in home care settings. But its interface features, such as difficult data entry in writing and small display screen, still confine its use. We developed a PDA information representation approach which had been practically proven to be easy to use by nurses [2][3]. A modified version was latter developed for the long forms.

The purpose of this study was to use the modified PDA information representation approach to design the PDA-based MDS home care evaluation support system and to examine the home care nurses' acceptance of the PDA-based MDS-HC system.

Methods

The modified PDA information representation approach is mainly composed of 4 principles:

1. The screen display area is separated into three sections for the users to clearly see and to easily navigate through the form.

2. User should be able to switch to any item in less than 3 taps.

3. The hand-writing should be replaced, if possible, by tapping for data entry.

4. User should be well reminded what tasks have been done.

A team of nursing user, nursing programmer and experienced PDA programmers was organized and the prototyping approach was used to develop the system. A convenient sample of 24 subjects, who were trained of the MDS, was used for testing. 3 representative home care scenarios were written for users to test the PDA system. Davis' Technology Acceptance Model was used to evaluate users' acceptance of the system in terms of their perceived ease of use and usefulness.

Results

The representative PDA screen was shown in Figure 1, in which uses could navigate the system through tapping the upper main category and subcategory buttons, and enter data in the lower half data entry area. The highlighted buttons mean answered questions.

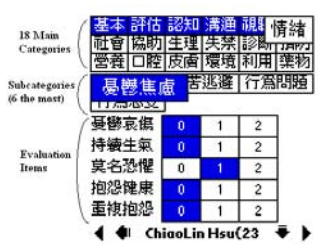

Figure 1. The representative screen shot.

Figure 1 - The representative screen shot

58% of subjects never used the MDS-HC form. Most of the subjects have BS degree and aged from 20-50. 100% agreed the system was easy to use and 92% agreed the system was useful.

Conclusions

Our study showed that a well-usability-engineered PDA system can well improve the usability of both the professional forms, which was too long to be practically accepted, and PDA, which small-display interface usually hinders its popularization.

[c] *Indiana Health Information Exchange*

Abstract

In an effort to provide decision support during times of public health emergencies, Regenstrief Institute, Inc. and the Indiana University School of Medicine, in partnership with the county and state health departments, created a sustainable model to deliver information to health care providers and public health workers. The model leverages extant systems and processes, including active surveillance through electronic laboratory reporting, delivery of health information as part of the Indiana Health Information Exchange, and evidence based utilities and Blog technology to create a public health utility with disease specific information and epidemiologic reporting requirements.

Keywords:

disease outbreaks; bioterrorism; information dissemination; decision support systems, clinical

Introduction

Knowledge at the point of decision making is critical to improving health care and this is especially true in public health when medical decisions in response to a bioterrorist event or an emerging epidemic could have a much greater impact. However, the ability to access such information has been extremely problematic because of the different levels of connectivity and training available to public health workers and health care providers across large areas.

To address this issue a partnership was formed among the Indiana State Department of Health and the Marion County Health Department, the Indiana University School of Medicine Libraries (IUSML) and the Indiana Health Information Exchange to establish a cost-effective model for both alerting health care providers and public health workers to developing threats and providing them the needed information for both treatment and reporting.

Methods

The model, predicated on an earlier construct [1], was built on three existing programs. The Regenstrief Institute, Inc. in conjunction with the Indiana Network for Patient Care and the Indiana State Department of Health developed an active surveillance of reportable conditions program with electronic laboratory reporting. [2] I3, the Indiana IAIMS (Integrated Advanced Information Management Systems) Initiative, through the Indiana Health Information Exchange and its DOCS4DOCS utility, provided a framework to notify health care providers about real or suspected public health emergencies. [3] The IUSML offered evidence based decision support using Web technologies.

The goals of the project were to insure rapid notification of public health problems to a large yet appropriate group of health care providers and to provide access to quality filtered knowledge supporting treatment guidelines and reporting requirements. Because the eventual objective was to operationalize the model for long term adoption, it was essential to develop sustainable methods.

Electronic laboratory reporting uses LOINC coding and HL7 messaging to provide timely information to the health departments regarding the potential for a public health event. Notifiable conditions from laboratories around the Indianapolis metropolitan statistical area are reported to the health departments. The enhancement model facilitates provider notification and the creation of decision support information.

The health care provider indexing in the Indiana Health Information Exchange enables the rapid notification of health care providers about emerging public health threats based on location and/or condition. This insures a higher level of relevance of the warning for the provider. Simultaneously, the IUSML is contacted about the suspected problem and receives information concerning proposed optimum treatment and management guidelines and the required reporting of the specified condition.

The IUSML is responsible for searching for current evidence about management of the condition and creating a web presence containing this information in a user effectiveness format. In addition, reporting requirements and links to the health department web sites are included. To insure sustainability, a Blog utility was chosen because of its ease of document creation and maintenance, the famil-

iarity of the format for most users, and its functionality in searching for prior conditions.

In addition to the reporting and management information for health care providers, a listserv is maintained for notification of public health workers. The health departments have their own systems for notifying their affiliated sites, however the notification of access to knowledge-based information is handled by the IUSML once the Blog site has been updated and approved.

While most of the information about emerging public health events comes from the electronic surveillance functionality, some comes from the public press. While this usually involves very specific localities and has little potential to develop, decision support is also beneficial for these events and the Web site is updated as the need presents itself.

Results

As of November 2006, there were thirteen public health events that prompted the creation of knowledge support on the Web site. The mechanism for the notification of health care providers has been developed using extant resources but has as yet to gain widespread adoption, not because of the technology but because of organizational issues.

The process for the notification of public health workers was implemented with the second public health event posted and, as a result, the utility has achieved wide spread use. Anecdotal responses to the initiative have indicated that the Web site has provided critical information for both management of health care conditions and epidemiologic reporting.

Discussion

By using three extant processes, active surveillance through electronic laboratory reporting, DOCS4DOCS delivery of information to health care providers, and the evidence based medicine services of the IUSML, a sustainable model was developed to deliver decision support information to targeted health care providers and public health workers during instances of public health events.

The technology and processes were easily adapted to meet the needs of the health departments and system users. However, organizational issues regarding the health care provider notification component have precluded the full operationalization of the system. It is anticipated that these issues will be resolved within the next year and that the system will be fully implemented. However, the public health worker notification and the creation and use of the Blog utility have proven to be an effective means to providing decision support during times of emerging infectious diseases and bioterrorism events.

Conclusion

Emerging public health crises require coordination of information from a variety of sources and targeted provision of quality filtered knowledge to a wide range of health care workers. Access to evidence is critical to the management of the events for both the population and individual patients; collecting information to monitor the impact of the occurrences contributes to the knowledge base and helps mitigate future occurances. Using extant technology and promoting organizational partnerships can offer a sustainable model to enhance responsiveness to these events.

Customized Early Warning System Based on HTN for Home Healthcare Model

Seung-Jin Jang[a], Jip-Min Jung[a], Sung-Oh Hwang[b], Young-Ro Yoon[a]

[a] *Department of Biomedical Engineering, Health Science College, Yonsei University, Wonju, South Korea*[b]*Department of Emergency Medicine, Wonju College of Medicine, Yonsei University, Wonju, South Korea*

Abstract and objective

We adopted hierarchical task network (HTN) planning in a customized early warning system for home healthcare model. It is necessary to design a customized early warning system for the patients who were in various health states, because regular or irregular report format and alarm delivery systems were diversified according to severity of health state. HTN planning is suitable for use of constraint programming so as to effectively prune the search space during the search for solution. An efficient and scalable information control is presented by use of HTN. The paper also briefly deals with a process strategy for the early warning system.

Keywords:

hierarchical task network, emergency response, home healthcare model

Introduction

As the elderly population and the demand of well-being life increasingly grow, IT-based technology allowing bio-signal measurement and assessment at home have been focused nowadays. The elderly or citizen can be efficiently controlled with respect to health status parameters which act as input features in the early warning system for health status.

Methods & results

The early warning system developed by Home Healthcare Management System Research Center (H2MSRC) in Yonsei University adopted HTN planning in order to efficiently design the planning of emergency response because of extendible, intelligible, and easily communicated properties. Events derived from 7 objective status parameters measured from 4 types of sensor devices and 3 subjective parameters results in customized emergency response according to the formalized SHOP domain model. (Ref. figure 1)

Conclusion

HTN planning was practically adopted in our early warning system for Home healthcare model and revealed the intelligent and collaborative planning ability.

Open Source Patient Data Management System for Intensive Care

Massaut J, Reper P, Hooghe L, Gottignies P

Surgical Intensive Care, Brugmann Hospital, Université Libre de Bruxelles

Abstract and objective

In Intensive Care Units, the amount of data to be processed for patients care, the turn over of the patients, the necessity for reliability and for review processes indicate the use of Patient Data Management System (PDMS). To respond to the needs of a Surgical Intensive Care Unit, we developed a PDMS based on open source software and components.

The software was designed as a client–server architecture running on the Linux operating system and powered by the PostgreSQl data base system. The client software was developed in C. The application offers the following functions: medical notes captures, observations and treatments, nursing charts with administration of medications and scoring systems functionalities. The PDMS was used to care more than two thousands patients with the expected reliability and functionalities.

Key words:

database management system, software, intensive care

Introduction

Patient Data Management Systems are mandatory in Intensive Care Unit in response to the amount of data to be processed, the turn over of the patients and the necessity for review processes. To respond to the needs of our unit we developed a PDMS based on open source software and components.

Methods

The software was designed as a client-server architecture running on the Linux operating system (SUSE Linux Enterprise Server 8.0), using the PostgreSQL relational database (v 7.2). The client software was developed in C using the GTK interface library. Remote access from remote PCs is implemented by virtual network connections (VNC), the use of VNC servers and VNC viewers.

The hardware consists in two Intel x86 servers (one master and one slave to assure the integrity of the database by replication),

14 medical grade panel PCs connected via RS232 medical bus to the patient's monitoring devices and the servers via local Ethernet network.

The software, developed on the Linux platform, offers the following functions: medical notes captures with patient's history, observations and treatments, nursing charts with functionalities for administration of medications, and scoring system possibilities for patient's classification. Interoperability between these modules is realized through access to the PostgreSQL database and not the use of local memory in the interface. The software was developed to be open source in all its components.

Results

The PDMS is in used in our unit from February 2004 and was used to care more than two thousands patients. The system is accessible at every bed through panel PCs and at desks or offices through VNC viewers on windows PCs. Its design allows an access to the database's functionalities with a high availability level (less than 5 hours of interruption over one year).

The use of open source resources was effective to customize the solution to ICU's request. The use of the C language permitted to obtain small response times but limits the portability of the system and complicated the debugging process in this critical environment.

Conclusion

PDMS based on open source software components are effective and able to respond to the needs of the ICU environment, with a high availability level.

Why Teach Computer Security to Medical Students?

Ana M. Ferreira [ac], Ricardo Cruz-Correia [ab], Altamiro Costa-Pereira [ab]

[a] *CINTESIS - Center for Research in Health Information Systems and Technologies, Faculty of Medicine of Porto* [b] *Biostatistics and Medical Informatics Department, Faculty of Medicine, University of Porto* [c] *Department of Informatics, Faculty of Medicine, University of Porto*

Abstract

The introduction of Electronic Medical Records (EMR) within the healthcare practice can be beneficial in order to integrate and centralize heterogeneous patient information. However, there are still some problems that hinder the successful use of EMR. The concern for patient privacy is one of them. The aim of this paper is to present the results of a study that assesses attitudes of 1st year medical students towards computer security and the EMR. An anonym questionnaire was given to the students at the beginning and at the end of the academic year of 2003/2004 for them to comment on several security related scenarios. 238 questionnaires were answered at the beginning of the year whilst 222 were answered at the end of the year. The students feel, at the end of the year, that they understand better what computer security is and how to protect patient privacy information. This shows that teaching computer security to medical students, the future users of EMR, can greatly influence the success of EMR integration and therefore improve and fasten healthcare treatment.

Keywords:

computer security; education, medical, undergraduate

Introduction

The introduction of Electronic Medical Records (EMR) within the healthcare practice allows for the integration of heterogeneous information that are usually scattered over different locations [1] [2]. However, there are some barriers that impede its successful integration in most healthcare practices [3] [4].

One specific barrier relates with the privacy and security of patient information [5]. The use of new information systems within healthcare stresses the need for young doctors to comprehend them from their conception so that they can be used in a beneficial way and support their future daily work. As such, all the feedback provided during their training into the medical profession is essential for the enhancement of those systems [6], moreover in terms of computer security.

The Biostatistics and Medical Informatics Department of Porto Faculty of Medicine teaches Ethics and Medical Informatics to 1st year medical students [7]. The later subject includes theoretical and practical lectures about Electronic Medical Records (EMR) and computer security.

This study aims to assess the opinions, attitudes and awareness of 1st year medical students towards computer security issues relating to EMR, and how these can affect the successful integration of EMR within the healthcare practice.

Methods

An anonym questionnaire was given to the students both at the beginning and again at the end of the academic year of 2003/2004. It was applied two times so that we could compare their attitudes before and after they had attended the Ethics and Medical Informatics' subjects.

The questionnaires introduced 3 scenarios for the students to comment. The first scenario described a breach of patient privacy to an EMR by one of their colleagues. There were two questions relating with this scenario:

- Q1.A – Is the described scenario a security breach?
- Q1.B – What would you do if you found out about this breach?

The second scenario included additional information to the first scenario. It explained that the colleague in question had shared his password with a friend and that friend was the one to access patient private information, without him knowing it. The question related with this scenario was:

- Q2 – Would you change your attitude if you found out this new piece of information?

The third scenario introduced the issue of more sensitive information (e.g. HIV, Cancer results or even VIP related) and how this information must be protected. The question presented within the questionnaire was the following:

- Q3 – Do you think this kind of information requires stronger security measures than other types of information?

The answers to these questions were inserted into SPSS® and analysed separately.

Results

A total of 460 questionnaires were filled by the students. 52% (238) were answered before the lectures started whilst 48% (222) after the lectures finished. Table 1 shows the results obtained from the applied questionnaires.

Table 1 – Results obtained from the questionnaires

		Before the lectures % (n)	After the lectures % (n)
Answered questionnaires		*(238)*	*(222)*
Q1.A	*Valid answers*	*98 (232)*	*98 (217)*
	Yes	100 (232)	100 (217)
Q1.B	*Valid answers*	*61 (144)*	*60 (132)*
	Reason with	54 (77)	44 (58)
	Inform	40 (58)	50 (66)
	Others	6 (9)	6 (8)
Q2	*Valid answers*	*62 (148)*	*62 (138)*
	No	74 (109)	83 (115)
	Yes	26 (39)	17 (23)
Q3	*Valid answers*	*43 (103)*	*91 (204)*
	No	44 (91)	38 (77)
	Yes	55 (112)	62 (127)

For Q3, the main reason given by the students that felt no extra security measures were needed to access more sensitive information is that all security measures must be effective for all cases, independently of the patient or healthcare performed. The majority of the students that thought extra security measures were necessary agreed that this would provide for the protection of certain social groups from discrimination.

Conclusion

According to this study's results, after Medical Informatics and Ethics' lectures, students feel more conscientious to report privacy breaches to responsible parties (Q1.B). They understand better what computer security is and how to behave in order to protect confidentiality of electronic information. They consider indirect disclosure of sensitive information, such as with another person's password, a serious fault (Q2). Further, at the end of the year, students become more aware for the need of different protection levels of security depending on how sensitive information can be (Q3).

We believe that the introduction of Medical Informatics and Ethics early in the degree of the Medical course has an influence in the awareness and attitudes of first year medical students towards computer security and EMR. This can greatly influence the success of EMR integration whilst improving and fastening healthcare treatment.

Application of Wireless and Mobile Computing Technologies to Improve the Efficiency of Patient Care and Education: The Role of Medical Engineering and Information Technology

Lin Guo

Centre for Adult and Paediatric Gastroenterology, Institute of Cell and Molecular Science, Queen Mary's School of Medicine and Dentistry Barts and The London, , Queen Mary, University of London, UK.

Abstract

This study explored the potential of the application of wireless and mobile computing technologies to be used in improving the efficiency of patient care and education and future developments in information and communication technologies to support healthcare professionals and medical students in healthcare research, medical education and training. The design used for this study was a systematic review of published materials obtained from EMBASE and MEDLINE online databases, and the Cochrane Library database, including personal observations. Today, more than 50% of healthcare professionals and medical students are using Personal Digital Assistant with expected growth of more than 75% by year-end 2007. In addition, wireless and mobile computing technologies allows Personal Digital Assistant to connect directly to networks or the Internet. Studies relating to processes of patient care and should evaluate mobile computing technologies as a potential timesaving tool. Wireless and mobile computing technologies is only beginning to take its first step in improving patient care and education. They have shown a positive impact on patient safety, health care efficiency, and ultimately patient satisfaction.

Keywords:

wireless and mobile computing technologies, patient care and education, efficiency, personal digital assistant

Introduction

Wireless is a term used to describe telecommunications in which electromagnetic waves (rather than some form of wire) carry the signal over part or all of the communication path.[1] Mobile Computing is a generic term describing your ability to use technology 'untethered', that is not physically connected, or in remote or mobile (non static) environments.[2] The term of wireless and mobile computing technologies is evolved in modern usage such that it requires that the mobile computing activity be connected wirelessly to/through the application of internet or to/through a private network. This connection ties the mobile device to centrally located information and/or application software through the use of battery powered, portable, and wireless computing and communication devices.[1, 2] This includes devices like laptops with wireless LAN or wireless WAN technology, smart mobile phones, wearable computers and Personal Digital Assistants (PDAs) with Bluetooth or IRDA interfaces.

This study explored the potential of the application of wireless and mobile computing technologies to be used in improving the efficiency of patient care and education and future developments in information and communication technologies to support healthcare professionals and medical students in healthcare research, medical education and training.

Design and methods

The design used for this study was a systematic review of published materials obtained from EMBASE and MEDLINE online databases, and the *Cochrane Library* database, including personal observations. Materials that match the set criteria on the application of wireless and mobile computing technologies in medical engineering and information technology research for healthcare professionals and medical students to improve the efficiency of patient care and education were selected and analysed following the United Kingdom National Health Service Centre for Reviews and Dissemination Guidelines. A variety of data collection approaches were developed to ensure data were collected on the various aspects.

Results

Wireless and mobile computing technologies is seen to be convenient to get in touch, compact, fast and portable, but problems are attached to the levels of security, confidentiality and scalability of the hardware. It is also apparent that most commonly used wireless and mobile computing technologies within the health contexts is the Personal Digital Assistant. Today, more than 50% of healthcare professionals and medical students are using Personal Digital Assistant with expected growth of more than 75% by year-end 2007.[3] Not only can the healthcare professionals and medical students use the tool on the Personal Digital Assistant as a quick look-up resource at the bedside, but can also flag a topic for further research when back in the office. Changes in treatment guidelines, concerns about patient safety, efforts to contain costs, time limitations, and better informed patients make it critical to have clinical reference information at the point of patient care and edu-

cation.[4] In addition, wireless and mobile computing technologies allows Personal Digital Assistant to connect directly to networks or the Internet.

Discussion

According to the results of this systematic review of this study, wireless and mobile computing technologies has become a valuable resource for both healthcare professionals and medical students over the past decade. This has enabled new perspectives to be developed on the interface between hardware, software and education and training processes for those involved in delivering healthcare research. Studies relating to processes of patient care and should evaluate wireless and mobile computing technologies as a potential timesaving tool, as they can be synchronised with hospital information systems to facilitate retrieval of patient information. The findings also indicate that the healthcare professionals and medical students would benefit from some technologies that they can easily use to search for such sources as database, E-journals and the Internet. At a theoretical level, wireless and mobile computing technologies such as Personal Digital Assistant is ideal for meeting these needs. Further study on processes of patient care and education should also explore wireless and mobile computing technologies as vehicles for disseminating evidence-based guideline recommendations.

Conclusion

Wireless and mobile computing technologies is only beginning to take its first step in improving patient care and education. They have shown a positive impact on patient safety, health care efficiency, and ultimately patient satisfaction. The integration of the Internet and wireless and mobile solutions will transform the use of information and communication technologies in patient care and education and take it in the role of medical engineering and information technology. The potential of wireless and mobile computing technologies is vast and its principles, application and practices are seen as a choice for healthcare professionals and medical students to be in the right place at the right time. In the future we will see more valuable resources in improving patient care and by developing wireless and mobile computing technologies.

Comparing Messages in an Online Communication Forum for Cancer Patients with Patients' Messages to a Clinical Nurse Specialist

Annette Jeneson MA, Trine Andersen RN, Cornelia Ruland RN, Ph.D

Center for Shared Decision Making and Nursing Research, Rikshospitalet-Radiumhospitalet Medical Center, Oslo, Norway

Abstract

WebChoice is an online support system where cancer patients can exchange messages with other patients in an open communication forum as well as send personal e-mails to a clinical nurse specialist (CNS) who responds to their concerns. We compared the content of messages posted in the open forum with personal e-mail messages sent to the nurse. While patients were concerned with similar topics in both communication areas, there were differences in the types of messages sent. More patients actively used the patient-nurse email service compared to the forum, suggesting that nurses can play an important role in online systems supporting cancer patients over the Internet.

Keywords:

online systems, communication, nurse-patient relations, neoplasms

Introduction

Despite a growing interest in online support forums and patient-provider communication systems, knowledge of the relative use and benefits of these communication systems is still limited. In particular, there is little information about how patients' communications with care providers online differ from communications in discussion groups. Additionally, while a few studies have analyzed online messages between patients and physicians, online patient-nurse communication and the potential for nurses to support patients via the Internet is as of yet largely unexplored. The purpose of this study, therefore, was to compare the content of patient-nurse messages to messages posted on an online discussion forum for cancer patients. The study is part of a larger ongoing trial testing the effects of WebChoice, an internet support system for breast- and prostate cancer patients [1]. WebChoice includes tools for symptom monitoring, tailored information to support self-management, support forums for anonymous group discussion, as well as a more "private" communication area to exchange messages with a CNS specializing in cancer care.

Methods

We examined forum postings and e-mail messages by patients who logged on to WebChoice at least once from March - October 2006, resulting in a sample of 355 postings and 174 e-mails. Messages were coded according to the 'type' and 'topic' categories listed in Table 1 below. The 'type' categories are consistent with the coding schema of Klemm *et al* [2]. A message could belong to more than one category. An e-mail with questions about lymphedema and anxiety, for example, would be coded as *information seeking* for 'type', and *symptoms* and *feelings* for 'topic'. Messages were independently coded by two of the authors (AJ and TA) and 10% were coded by both to compare interrater agreement, established at 98 % for e-mail messages and 97 % for forum postings.

Results

Table 1 shows the percentages of e-mails and forum postings coded under the various 'type' and 'topic' categories.

Table 1. Percentage of messages categorized by type and topic

		E-mails (*174 total*)	**Postings** (*355 total*)
TYPE	Personal experiences/ opinions	66	75
	Information giving	2	20
	Information seeking	62	20
	Encouragement / Support	0	17
	Thanks	22	8
TOPIC	Health personnel / institutions	21	20
	Treatment / Tests / Test results	63	59
	Symptoms / Side-effects	64	66
	Energy / Fatigue / Sleep	9	10
	Feelings	14	10
	Sexuality / Partner	3	7
	Family / Colleagues / Others	5	3
	Living with cancer / Lifestyle	22	23
	Metastasis / Relapse	7	8

The average number of topic categories per e-mail or posting was 2.4 (±1.5) and 2.3 (±1.3), respectively. As seen in Table 1, patients were concerned with largely the same topics in their e-mail messages and in their forum postings, but the type of message or posting varied, with e-mails being more 'information seeking' in nature and postings being more 'supportive' and 'information giving' to others.

There were also differences in use of the e-mail component of the WebChoice system compared to use of the discussion forum in terms of the number of participants actively using these two different components. 71% of participants given access to WebChoice logged on at least once in the data collection period (43 females and 31 males). Of these active WebChoice users, more patients used the patient-nurse communication area (n=45 or 61% of WebChoice users) compared to those submitting messages to the forum (n=34 or 46% of users). This holds true for breast cancer patients as well as prostate cancer patients. 72% of female users who logged on to the system at least once between March to October 2006 sent at least one e-mail to the nurse while 58% submitted at least one posting. 45% of active male users sent an e-mail to the nurse while 29% contributed to the forum. However, while more patients wrote e-mails to the nurse compared to the number of patients who submitted a posting in the forum, those patients actively participating in the discussion forum submitted on average more postings (10.4±10.5) compared to the average number of e-mails sent to the nurse (3.9 ± 4.6).

Discussion and conclusion

This sample of messages and forum postings, although small, provide useful information for health professionals interested in online communication systems. In a number of computer-based support systems for patients the communication areas are consistently highlighted as the most popular sections of the system, yet our knowledge about patients' use and benefits of different features within these communication areas is limited. A preliminary usage analysis of WebChoice suggest the forum is so far the most visited section in this support system [3], but the fact that more patients submit messages to the nurse via e-mail compared to the forum, and that the nature of messages in these two communication areas differ, suggest that opportunities for patient-nurse communication can provide valuable support for patients beyond that of support offered by participation in online discussion groups. Patients often experience multiple symptoms during treatment and rehabilitation, yet short hospital admissions allow little time for detecting and relieving these. Moreover, side-effects of certain treatments are often worst after the patients are discharged to home.

Therefore, patients could greatly benefit from support through an Internet based system, where they can communicate with a care provider independent of scheduled hospital or doctor appointments in an environment that is readily accessible and even anonymous. In this sample almost all of the questions patients asked via e-mail could be appropriately addressed by the CNS and did not require advice from a physician or other specialist. This suggests that online communication with a nurse may potentially reduce not only needless patient suffering and worrying but also the numbers of doctor's appointments scheduled. As cost concerns and shortages of health professionals continue to rise, online peer- and professional support provided by nurses could prove a viable health care supplement that can improve delivery of high quality patient care in the future [4].

Acknowledgments

We thank Laura Slaughter and Gro Hjelmeland Grimsbø for helpful discussion. The research was funded by the Norwegian "Health and Rehabilitation" Grant # 2003/3/0429.

Guideline-based Visualization of Medication in Chronic Disease

Ján Stanek, Michelle Joy Davy

Advanced Computing Research Centre, University of South Australia, Australia

Abstract

Chronic disease management at the General Practice level is a challenging task requiring synthesis of information across time and possibly several practitioners. Sparsity of data, lack of structure, lack of time are limiting factors of computer use in this domain. Authors are exploring the concept of visualization of individual patient's medication using a clinical guideline to provide some structure to the problem by creating a state-transition model. This approach was shown to be promising at the practice level in previous research [1,5,6] where an overall synthesis of practice decisions was created and alerts were generated on the basis of individual transactions or states - current focus is on individual patient and the sequence of states describing his/her medication history.

Keywords:

general practice, visualization, decision support, guideline

Introduction

In managing chronic diseases, the information on the past course of the disease can be important - but many practitioners see reviewing of past data as a (necessary) evil to be done as quickly as possible [2]. With more and more general practitioners (GPs) using a computer in their everyday practice [3] it is more than tempting to use the existing data to provide support for quality and continuity of care. Typically the data is meant to be used by humans so the data is rather unstructured, with highly variable quality in terms of completeness or adherence to some coding standards. In a comprehensive review it was shown, that prescription data is the one most complete and reliable [4]. Assuming, that medication reflects significant proportion of decision-making about a case a guideline-based state-transition model was created and used for analysis at the practice level, as well as for generation of patient-related alerts [1,5,6]. While this approach shows promising results, information on patients as drawn from the model does not take into account patient-specific sequences of states. In the current work we explore the visualization of these sequences as well as generating alerts based on sequential patterns for particular patients in line with the ideas of Aigner and Miksch [13].

Materials and methods

The backbone of the study was a state-transition model focusing on treatment of hypertension in diabetes mellitus based on an American Diabetes Association guideline [7]. The data used in the study were de-identified extracts from a general practice in rural Australia holding age, gender, visit dates, problem codes, blood pressure measurements and drug prescriptions. The extracts covered 6 years and contain more than 70000 prescriptions. Two sequences of events/states were generated for each patient: prescription path and treatment path. Prescription path was shows just a sequence of drugs or they combinations as they were prescribed; while the treatment path shows a sequence of states as derived from the state-transition model

Treatment path

According to methodology described in [5] medications were clustered into 6 groups (group B has 3 subgroups):

- Group A: Angiotensine converting enzyme inhibitors (ACEi) - ATC codes C09A and C09C
- Group B1: -blockers (BB) - ATC codes C07AA, C07AB
- Group B2: Diuretics - ATC codes C03AA, C03CA or C03D
- Group B3: Non-dihydropyridine Ca-channel blockers (NCCB) - ATC code C08D
- Group C: Dihydropyridine Ca-channel blockers (DCCB) - ATC code C08CA
- Group D: -blockers, hydralazines, clonidine - ATC codes C02CA, C02DB, C02AC

In our study we deviated slightly from standard ATC coding - combination drugs were coded as if a set of separate drugs was given. This deviation was useful to simplify the model-building algorithms and did not have impact on the analysis.

Based on prescription data states were generated, using the amount and the daily dose of prescribed drug to calculate duration of treatment with a particular drug group. In this calculation we assumed, that patient starts the medication on the same day as it was prescribed, that the dosage is unchanged throughout the time covered by a particular prescription (and the patient adheres to the dosage).

Prescription path

A prescription is a sequence of prescription instances. A prescription instance is a drug, or combination of drugs as prescribed on a particular day, disregarding dosage or quantities prescribed.

All methods were implemented using Cache and Ensemble (Intersystems Inc.), graphs were generated using GraphViz software (www.graphviz.org).

Results

A prescription path and a treatment path were created for each patient. Both paths are shown simultaneously and provide different views on what was done. E.g. if a drug containing a BB and diuretic was prescribed and at the same time a potassium-sparing diuretic was prescribed the prescription instance is shown as B1+B2+B2; while the treatment path will show B1+B2 combination. A particular prescription path can have several treatment path counterparts (Figure 1).

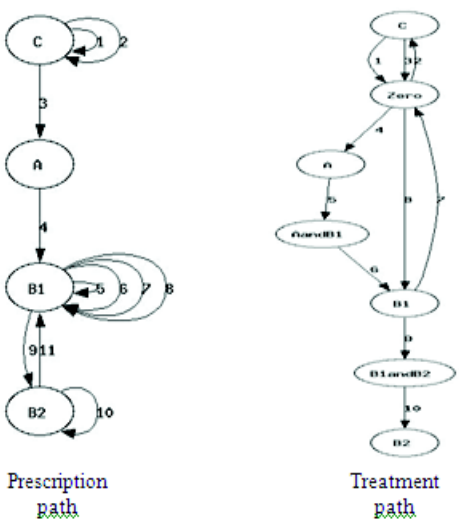

Figure 1 Prescription path vs. Treatment path

Alerts

Visualisation of the paths should be in most cases enough for an experienced GP to see any unusual patterns, however the results can be analysed in background and selecting only patients with an unusual pattern. Analysing treatment paths allows to create an additional class of alerts, taking into account more than just one state or one transition. More than just the preceding state (eventually the whole path) can be taken into account in launching an alert - e.g. transition from A to B1 as well as transition from B1 to A might be OK per se, but if this is repeated more than **n** (usually 2-4) times, it may be considered an unusual pattern and an alert should be launched.

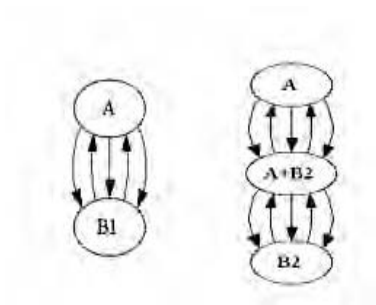

Figure 2 Cyclic patterns in treatment paths

Discussion

Guideline can be utilized at two levels in data analysis. First approach is to use the guideline to structure the problem space and then fit the data into the resulting of structure. Svátek and íha [8,9] used a guideline to lead a data-mining exercise in their analysis of guideline compliance in hospital environment. This idea is similar to what we use, however it was applied in a much better controlled environment of a large hospital. Others [10, 11, 12] focussed more on intentions and worked in a hospital, data rich setting. Major advantage of this approach is, that results are presented to the physician in the context of the guideline making it easier to recognise and appreciate the rationale behind the graphs and alerts.

Alternate approach is to use data mining techniques to raw data and then compare the results to a guideline. Possible method of creating similar results to ours is path or workflow mining (e.g. [14]). This approach can be exploited either to improve the guideline or to detect exceptions in clinical workflow.

Conclusion

Authors extended the scope of previous research [1] by adding visualizations for individual patients as well as new types of alerts taking into account more than just one transition or just one therapeutic state. This approach is to be validated by a clinical study in next future.

Acknowledgments

The study protocol was approved by the Human Research Ethics Committee of the University of South Australia (protocol P005-04) and undertaken with a Memorandum of Understanding with Lubims Pty. Ltd. Special thanks to Intersystems Inc. for providing licenses for Cache and Ensemble.

Efficiency and Safety of New Radiofrequency Identification System in Japanese Hospital

Yuichiro Saito[a], Takashi Hasegawa[b], Tetsuo Sakamaki[c]

[a]*Division of Cardiovascular Medicine, Gunma University Hospital, Maebashi, Japan*
[b]*Informatics Education Center , International University of Health and Welfare, Tokyo, Japan*
[c] *Medical Informatics and Decision Sciences,Gunma University Hospital, Maebashi, Japan*

Abstract and objective

Radiofrequency identification (RFID) uses radio-frequency tags attached to people or objects to provide identification, tracking, and security under the general heading of automatic identification. New RFID system (UHF band, 953 MHz) has been available since April, 2005 in Japan. We tested efficiency and safety of new RFID system in our hospital. Electric fields produced by new RFID had no significant effects on cardiac pacemakers, implantable cardioverter defibrillators (ICD), and other medical devices□@(ex. Electrocardiogram recorder, cardiac monitor, intra-aortic balloon pumping, infusion pump, and respirator) in our hospital. New radiofrequency tags seemed to provide extensive patient identification and to track capital equipments within our hospitals. Healthcare systems today are increasingly complex and interrelated processes, while new RFID technologies will provide opportunities for enhanced patient care and safety in Japanese hospital.

Keywords:

cardiac pacemaker, implantable cardioverter defibrillators, healthcare, patient safety

Introduction

Radiofrequency identification (RFID) has recently begun to receive increased interest in supply chain, in order to increase the efficiency and visibility of material and information flows. RFID may address to improve safety and increase in productivity. New RFID system (UHF band, 953 MHz) has been available since April, 2005 in Japan. However, there has been no attempt to determine whether electric fields produced by new RFID can influence cardiac pacemakers, implantable cardioverter defibrillators (ICD), and other medical devices in our hospital. We further examined to track new IC tags attached to people and medical equipments in hospitals.

Our data may provide the potential benefits, the area of applications, and the corresponding strategies of RFID in hospital environments.

Methods

We examined effects of RFID system on 7cardiac pacemakers and 5 ICDs in 0.18 % salt solution, similar electric condition to human body. The experimental conditions for interference induced by RFID were between a homogeneous electric field perpendicular to the area formed by the antenna and radio-frequency tags.

We next tested whether Electrocardiogram (ECG) recorder, ECG monitor, intra-aortic balloon pumping (IABP), infusion pump, and respirator in our hospital could work normally under new RFID system.

Furthermore, we evaluated to track new IC tags attached to people and medical equipments in our hospital.

Results

Electric fields produced by RFID had no significant effects on cardiac pacemakers. There was no differentiation between a unipolar and a bipolar system. The RFID systems did not interfere with ICDs.

ECG recorder, ECG monitor, IABP, infusion pump, and respirator were worked normally under operation of RFID systems.

Radiofrequency tags attached to people and capital equipments within our hospitals provide more extensive identification than traditional bar coding can.

Conclusion

RFID may be ultimately used for many of the functions currently carried out using bar coding if the cost of RFID comes down. Healthcare systems today are increasingly complex. RFID is a technology that will have a profound impact on effective and safe patient care in Japanese hospitals in near future.

Development of Hypertension Management Ontology for Guideline-based Clinical Decision Support System

JiHyun Kim[a], InSook Cho[b], EunJung Lee[a], JaeHo Lee[c], Yoon Kim[d]

[a] *Center for Interoperable EHR, Korea*
[b] *Department of Nursing, Inha University College of Medicine, Korea*
[c] *Department of Emergency Medicine, University of Ulsan College of Medicine, Korea*
[d] *Department of Health Policy and Management, Seoul National University College of Medicine, Korea*

Abstract

For knowledge representation of guideline based hypertension management, hypertension management ontology was developed. Ontology was adopted as a method for enabling to share and to reuse knowledge of a domain with consistency in this study. This work is an essential course in representing knowledge in a computerized method and enables to reuse knowledge in interested domain areas. On the basis of published guidelines including JNC 7, concepts related to hypertension management knowledge and relations between concepts were made and defined. Entities of concept were defined. This ontology includes high level 11 classes and about 300 concepts and it defines instances of each concept. This work will be use useful to build a tool in order to acquire specific domain knowledge and contribute to spreading knowledge sharing and standardized clinical guidelines.

Keywords:

ontology, hypertension management, computerizing clinical guideline, knowledge representation

Introduction

In Korea, the Government leads Electronic Medical Record (EMR) development for the 152 primary health centers, which is planned to be expanded to Electronic Health Record (EHR) system. As a part of this work, development of clinical decision support system (CDSS) is in the process of advancing. This study describes a part of constructing the guideline based decision support system for hypertension management in primary care setting and encoding hypertension management knowledge. This is essential for representing knowledge in a computerized method. It is for reusing knowledge in interested domain areas.

For knowledge sharing nationally, knowledge management method, such as ontology is main issue on the aspect of clinical decision support system and others. Ontology is a methodology to formalize a shared understanding of a domain and enables to share and reuse of knowledge consistently between software applications and humans.

Materials and methods

This ontology is primarily based on 12 published hypertension guidelines including JNC 7. Concepts related to hypertension management were defined at the modeling stage and defined concepts were classified according to semantic category. Relations and attributes of concepts were defined. We authored knowledge in Protégé 3.1.1 environment.

Results

About 300 concepts related to hypertension management were defined. A medication prescription, laboratory test, physical examination, and other related conditions were included in related concepts. Based on the concepts defined, high level classes which contained medication, clinical finding, test, patient education, problem, patient case, event, rule, therapy adjustment, temporal predicate, and eligibility criteria were made and defined. Each class included subordinate concepts of is-a relation. Then, attributes of concepts were defined. Completed ontology had 11 classes and about 300 concepts.

Conclusion

Through this approach, Creation of a tool to acquire particular domain knowledge is expected to be easier. Furthermore, the ontology of hypertension management for guideline based clinical decision support system is considered to contribute for sharing and disseminating knowledge and to spreading standardized clinical guidelines through reusing knowledge.

Secure Remote Access for Web Based Clinical Information System Using Policy Control of PCs and Healthcare PKI Authentication

Katsuya Tanaka[a], Mayumi Yoshida[b], Ryuichi Yamamoto[b]

[a] *Department of Planning, Information and Management, University of Tokyo Hospital*
[b] *Interfaculty Initiative in Information Studies, Graduate School of University of Tokyo*

Abstract and objective

This paper describes a robust method of secure remote access for Web based clinical information system using Health-care PKI authentication. It enables medical staffs to refer the medical data using his own PCs from their home or their mo-bile phones over the Internet. This system contributes to re-duce strain of medical staffs especially in such institutes where intensive care is carried 24h/365d. For this purpose, it must permit the remote access to the hospital information system from PCs in various conditions, it is necessary to establish a secure connection using VPN or SSL, and control the policy of client PCs for the prevention of computer virus effect etc., and at the last, confirm user authentication with strict identification using Healthcare PKI (HPKI).

Keywords:

healthcare PKI, clinical information system, secure remote access control, VPN

Introduction

In Japan, healthcare ICT is promoted by Japanese government and in this year, the government made "New IT Reform Strategy" and "The Action Plan 2006". It emphasizes the reengineering in the healthcare field using ICT. It includes some actual plan such as constructing secure and reliable network for regional and inter-regional cooperation, introduc-ing smart cards for healthcare, and development of Health-care PKI (HPKI) which is based on ISO 17090. Actually we started to use HPKI in 2004, as a demonstration experimental system in the University of Tokyo Hospital for secure remote access to the medical data. HPKI was used in this system for authentication purpose, with verification the attributes of the national licenses of healthcare professionals, such as medical doctors, registered nurse, etc. By using this system, a physician can access the medical data of his patients with his own PCs even in his home or his mobile phones.

Methods

In our hospital, medical staffs are able to access to medical records using web based system in addition to special client PCs. Mainly based on the web interface, the following parts were also developed.

1. Certification Authority (CA)

For the convenience of user registration operation, All CA function was implemented in a note PC. It is also used for registering HPKI certificate to USB token.

2. VPN gateway

The connection between the hospital network and a client PC is established using IPSec. We picked a VPN gateway, Cisco Systems/VPN 3005.

3. Policy Control System

At the establishment of VPN connection, the server side policy is downloaded to the client PC, and during the connection, client PC is under the predefined policy. We picked Zone lab/Integrity.

4. USB Token for HPKI

At the insertion of this USB token, HPKI certificate is copied to the certain repository in Windows, and on the removable of token, the repository is cleared.

5. Reverse Proxy Server

For the verification of the HPKI certificate, especially hcRole attribute, user access is only allowed via this SSL reverse proxy server. At the connection to an internal web server in hospital, the user certificate in client PC is pushed and verified. For the mobile access over the Internet not using HPKI, we developed CHTML converter gateway. The identification number of each mobile phone is stored at the registration in server side, and the access of unknown device is prohibited.

Results

Over 30 doctors participated in this experiment and the developed system is now in use. This system is effective to check the results of emergency laboratory tests, or radiological images on PACS system from remote place. This system requires various client software, such as IPSec client software, USB token driver and policy control client, so it is difficult to manage for the user to install or operation. We are now discussing for the improvement of this system, such as using smart card for the HPKI token, SSL-VPN technology for an easy management of client PCs.

Infobuttons: A Study of Usability

Lily Gutnik[a], Sarah Collins RN, BSN[b], Leanne M. Currie RN, DNSc[a,b], James J. Cimino MD[a], and Vimla L. Patel, PhD.DSc[a]

[a]*Department of Biomedical Informatics, Columbia University, USA*
[b]*School of Nursing, Columbia University, USA*

Abstract and objective

Studies of clinician's information needs while treating patients have shown that the resolution of these needs is often deferred or fails, which may lead to medical errors. The Infobutton Manager was developed to help improve the resolution of information needs by providing users with links to on-line health information resources. The aim of this study was to determine the usability of the Infobutton interface to resolve clinicians' information needs. We provided clinicians with typical case scenarios using a computerized order entry system (CPOE) and Infobuttons and asked them to verbalize their thought processes as they were using the CPOE. We video-recorded the computer screens as the users worked, conducted brief exit interviews, and analyzed these data. Results indicated that the participants found the resources provided by Infobutton helpful and easy to use.

Keywords:

usability testing, clinical information needs, information retrieval decision support

Introduction

Though technology for clinical care is created to facilitate the clinician's workload and enhance patient care, tools that are inadequately designed can actually have adverse effects [1]. Inadequate design can result from a disconnect between the design process and the needs of the end-users [2]. Infobutton is a tool designed to provide clinicians with access to on-line health information resources to quickly resolve their information needs [3]. This study explored the usability of a new user Infobutton interface which was designed to be easier to read, more concise, and have more consistent navigation.

Methods

We conducted the present laboratory study to seek in-depth feedback from clinicians about the design and usability of Infobuttons within a CPOE system. Each participant was given three typical scenarios to be interpreted using the CPOE system and Infobutton. The computer screen was video recorded using Morae™ software. Participants were asked to "think aloud," that is to verbalize their thoughts. At the end of the session, the researcher conducted a brief exit interview. A previously established coding framework was applied to the data to characterize information needs.

Results

Two nurses, one physician, and one physician's assistant took part in the study, yielding a total of 79 information needs. Twenty-three of these needs (29%) were related to drug information, 28 (35%) concerned institutional procedures or policies, and the remainder were related to patient care and the treatment plan. Forty-eight information needs (60%) were successfully resolved using Infobuttons, 15 were deferred, and 14 needs failed to be resolved. Fifty-one needs (65%) were from an external source (e.g., Micromedex) and 26 (33%) were from an internal source (e.g., the local intranet). Exit interviews revealed an overall satisfaction with the resources provided by and the usability of Infobuttons. Excess information making navigation difficult was one of the problems identified.

Conclusion

Although clinicians show a high occurrence of information needs as they treat their patients, many of these needs can be met with Infobuttons All participants agreed that the information resources provided by Infobutton were valuable and easy to understand. This study imparted us with insight on the questions clinicians need to have answered for effective decision-making, and accentuated the need to be mindful of information overload.

The Application of A Clinical Data Warehouse to the Assessment of Drug-Warfarin Interactions

Qiyan Zhang[a*] PhD., Yasushi Matusmura[a] MD. PhD., Hiroshi Takeda[a] MD. PhD.

[a] *Department of Medical Informatics, Graduated School of Medicine, Osaka University*

Abstract and objective

Studies on drug-warfarin interactions in human subjects were typically based on single case reports or extrapolated in healthy volunteers. In this study, we proposed a method to apply an institutional clinical data warehouse (CDW) to address this issue in a real-world setting. A case-control study was conducted by using the CDW in Osaka University Hospital from 2000/01/01/-2005/12/31. We randomly selected the steady-state outpatients who were under warfarin mono-therapy as Group A and those who were on the pre-existing warfarin therapy but with only the added medication X as Group B. The difference between the PT-INR values on one-month interval in Group A and those before and after taking medication X for one month in Group B was compared. The warfarin-Allopurinol interaction was illustrated as one example. We identified 25 cases in Group A and 15 cases in Group B respectively. The difference of the PT-INR values on one-month interval between the two groups was not significant (P=0.394,Mann-Whitney test), indicating that no warfarin-Allopurinol interaction was present. This method can be used as an alternative approach to assess drug-warfarin interactions.

Keywords:

clinical data warehouse, warfarin, drug interaction, PT-INR

Introduction

Warfarin is an effective and commonly used oral anticoagulant agent for the treatment and prevention of thromboembolism in a variety of conditions. The risk of major complication- hemorrhage may be increased when concomitant drug therapy is required. Previous studies on drug-warfarin interactions in human subjects were based on single case reports or extrapolated in healthy volunteers. Clinicians need to balance the therapeutic benefits with the bleeding risk through monitoring patient's PT-INR values during warfarin therapy. In this study, we proposed a method to apply an institutional clinical data warehouse (CDW) in a real-world setting to reduce certain practical and ethical problems faced by studies drawn from healthy volunteers and aimed to provide an alternative approach to assess drug-warfarin interactions.

Methods

The CDW in Osaka University Hospital was built in 1995 as a subject-oriented database. The outpatient's prescription data and PT-INR results were picked up from 2000/1/1/-2005/12/31 through Business Objects 6.5.1. Data were processed via Microsoft Access 2003 and statistic analyses were performed via SPSS 11.0 Japanese Version for Windows. A case-control study was conducted. The steady-state outpatients who took warfarin consecutively for at least one month were considered as the eligible study subjects. We randomly selected those who were under warfarin mono-therapy as Group A and those who were on the pre-existing warfarin therapy but with only the added medication X as Group B. Then we compared the difference between the PT-INR values with one-month interval in Group A and those before and after taking medication X for one month in Group B. The warfarin-Allopurinol interaction was demonstrated as one example.

Results

For the chosen example, we identified 25 cases in Group A and 15 cases in Group B respectively. The difference of the PT-INR values on one-month interval between the two groups was not statistically significant (P=0.394,Mann-Whitney test), indicating that no warfarin-Allopurinol interaction was present. **Figure1**

Implementation of An Integrated Network for Health Research in Quebec.

Allen Huang[a], Jacques Lemieux[b], Jean-Claude Bouchard[b], Michel Bourque[b], Robyn Tamblyn[b]

[a] *McGill University Health Centre, Montreal, Canada*
[b] *Clinical and Health Informatics Research Group, McGill University, Montreal, Canada*

Abstract

Health data warehouses represent a valuable resource for health research. We have developed an infrastructure capable of providing health researchers in the province of Quebec with a toolkit to access the clinical data warehouses contained in the major academic health centres and the provincial health administrative systems. This demonstration will highlight the components that allowed the successful implementation of an integrated network to accomplish this task. Acceleration of the pace and increases in the volume and quality of health research within the province, in other jurisdictions and possibly world-wide is now an attainable goal.

Keywords:

health databases, information management, patient data privacy, database management systems, computing methodologies, health services research

Introduction

Health research done in the conventional, paper-record environment is tedious, expensive and reliant on data with varying quality. Large repositories of health data are invaluable resources to researchers and planners in health care. In the province of Québec, Canada, these repositories are housed in clinical data warehouses within the large teaching hospitals and the administrative data warehouse at the Régie de l'assurance maladie du Québec (RAMQ) – the provincial health services payer. The Infostructure de Recherche Intégrée en Santé (IRIS) - Québec project is a Canada Foundation for Innovation funded initiative to construct an integrated network for health research in the province. Its goal was to create secure access to these data warehouses, enable the linkage of patient records through the use of a provincial Master Person Identifier (MPI) and ensure that resultant datasets returned to researchers conform to privacy standards.

Methods

The IRIS-Québec architecture is a distributed, federated data warehouse model. The RAMQ already manages the MPI. The research warehouses of clinical data were constructed to ensure the highest standards of data quality. People: Researchers wishing to access these data warehouses no longer have to queue for specialized data analysts and programmers. The researchers' toolkit is a web-based, user-friendly interface that drives a powerful system with the following functions: selection of variables from the extensive data dictionary across the warehouses, building of complex queries using logical operators, a temporal relation tool to define time-dependencies of variables, a crosstabs manager, and a data extraction manager. Previously onerous and lengthy authorization steps have been streamlined into an electronic approval process which is reliable, timely and track able. Privacy: A novel "inference controller" was developed to ensure individual data privacy. This software computes the probability of the presence of an unique, potentially re-identifying profile when multiple databases are linked. The researcher's toolkit allows the dynamic modification of data query parameters in order to achieve the desired data precision without violating privacy rules. Processes: Data sharing agreements were established with each partner institution. Software agents were installed at each data source to manage queries, connectivity, linkages, and data flows. Each agent contains a copy of the inference controller engine. Performance: is maintained by de-coupling the phases of a research project from the raw data extractions. The creation of the complete cohort data cube is triggered only on submission of the finalized project profile. We will demonstrate the operation of the Toolkit through sample queries.

Conclusion

The architecture of our system can potentially be extended to other biomedical information sources such as genomics, proteomics and geneology databases and create new capacity for health and bio-medical research. This architecture can also be potentially replicated in other jurisdictions. Scaling such a system to the international level can result in enabling health and bio-medical research in the global community.

OpenECG: Promoting Interoperability Through the Consistent Implementation of the SCP-ECG Standard in Electrocardiography

Catherine Chronaki[a], Franco Chiarugi[a], Ronald Fischer[b]

Abstract and objective

The OpenECG Network (www.openecg.net) has been created to promote interoperability in electrocardiography with tutorials, specifications, open source tools, data sets, converters, and interoperability testing. ECG vendors, members of professional organizations, researchers, and other stakeholders participate in the OpenECG network to exchange views and receive assistance in implementation. In 2006, members are more than 700 individuals from 58 countries. A specific focus area for OpenECG that concerns diagnostic quality resting electrocardiograms (ECGs) is SCP-ECG, the European standard (EN1064:2005). An online interoperability testing service assists members in consistently implementing SCP-ECG and effortlessly integrating electrocardiographs with eHealth systems. OpenECG is a case of best practice in interoperability that should be followed by medical devices and sensors for effective personalized health monitoring.

Keywords:
interoperability, standards, telemedicine, eHealth services, medical devices, electrocardiography

Methodology

Electrocardiography is the most frequently applied non-invasive examination for early detection of heart disease, a leading cause of morbidity and mortality in western countries. It is estimated that more than 100 million ECGs are recorded annually in Western Europe. The ECG allows early detection and follow-up of heart disease, but today the operation of most ECG devices is still based on proprietary protocols and file formats.

SCP-ECG is a standard communication protocol that specifies the interchange format and a messaging procedure for ECG equipment-to-computer communication and for retrieval of ECG records from the computer to the ECG equipment (if needed). Since March 2005, SCP-ECG (EN1064:2005) is the European standard for high quality diagnostic ECG exchange and if consistently implemented ensures interoperability. Nevertheless, it is rather difficult for integrators to implement SCP-ECG correctly and there are variations in implementations, which can be a barrier to interoperability. Although a number of ECG device manufacturers and integrators have implemented the SCP-ECG standard, most implementations are not fully accurate. This is due partly to misconceptions and partly to the lack of widely publicized conformance levels and IHE-like integration statements that exist for modalities in radiology.

In 2003, OpenECG established an online conformance testing service to support the OpenECG community at large in implementing interoperable eHealth systems with SCP-ECG support. A member may submit an ECG file in an alleged SCP-ECG format and receive a list of errors and warnings. If no errors are detected, the submitter may request a certificate that is granted after thorough manual review of the file.

Results

The SCP-ECG conformance testing service has been used extensively by members and in many occasions an interoperable solution was achieved with support from the help desk. In the period 2003-2006, more than 1700 ECGs were submitted for conformance testing by members in more than 20 counties worldwide. Leading is Italy with 11 members, who have submitted 37.3% of the tests. After Italy, most ECGs have been submitted by Greece (17.74%) and Hungary (11.89%). ECG devices and eHealth services have been tested, improved, and validated using online tools and support from the OpenECG helpdesk. In 2005, a web service variant of the conformance testing service was integrated to the ECG viewer that won the first prize in the OpenECG programming contest. After certain limitations of the software were identified and amended, a new version of the ECG viewer was released and is currently available at the OpenECG open source repository.

Conclusions

The OpenECG network promotes best practice in interoperability for ECGs. Innovative eHealth services capable of managing personal wellness profiles call for plug-interoperability of medical devices, which is an issue of patient safety, key to advancing quality and cultivating consumer trust in the next generation of ambient intelligent working and living environments.
