

# Incremental Search for Counterexample-Guided Cartesian Abstraction Refinement

Jendrik Seipp Samuel von Allmen Malte Helmert  
University of Basel

## In a Nutshell

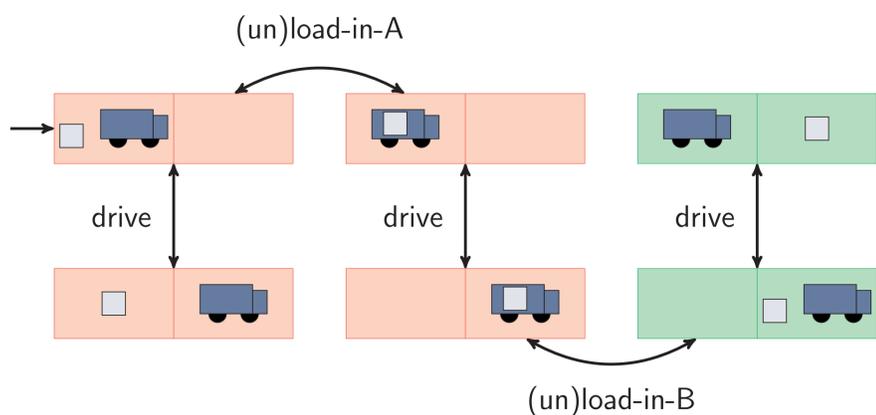

- ▶ optimal classical planning
- ▶ A\* search + abstraction heuristic
- ▶ counterexample-guided Cartesian abstraction refinement
- ▶ bottleneck: find shortest path
- ▶ incremental search: 1000x speedup

## CEGAR

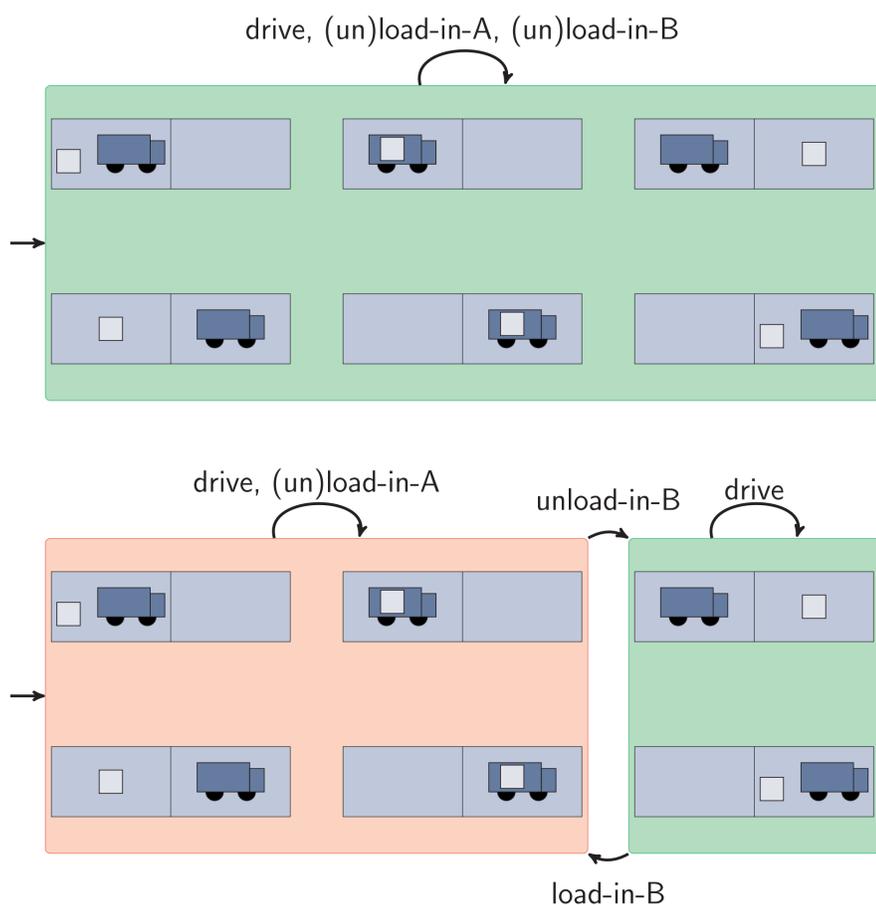

```

compute initial abstraction
until TERMINATE():
  find shortest path in abstraction
  if there is no path:
    return unsolvable
  find flaw in path
  if there is no flaw:
    return plan
  refine abstraction for flaw
return abstraction
    
```

## Example Task

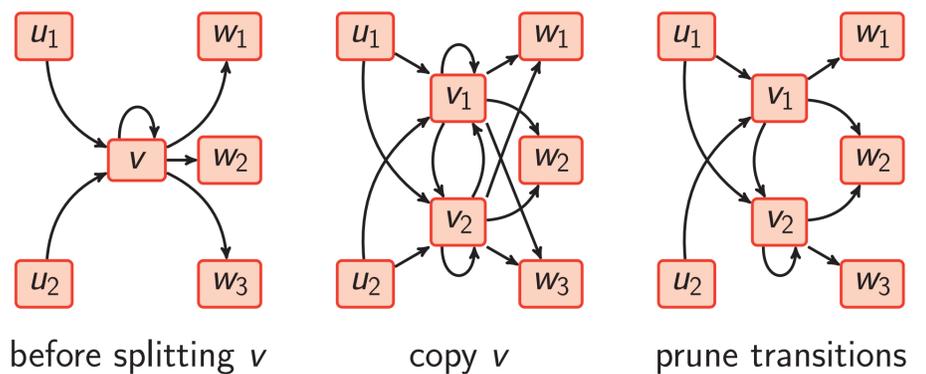

## Abstraction Refinement

## Incremental Search

- ▶ add/remove transitions
- ▶ increase/decrease weights
- ▶ fixed set of states

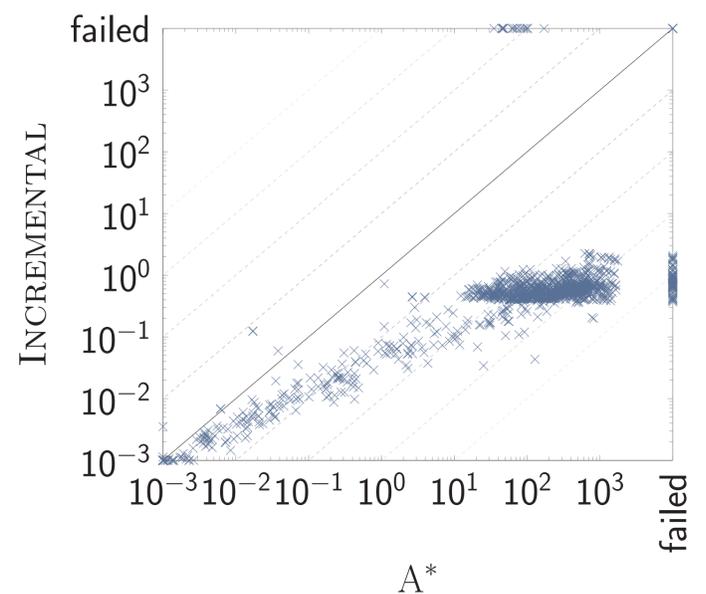

## Two-Step Refinement

## Increase (Frigioni et al., 2000)

- ▶ increasing weights, removing transitions
- ▶ shortest path tree
- ▶ reconnect ancestor states, mark rest dirty
- ▶ run Dijkstra on dirty states

## Time for Finding Shortest Paths

## Solved Tasks Over Time
