Abstract. We present AQQUA, a permissionless, private, and auditable payment system built on top of Quisquis. Unlike other auditable decentralized payment systems, AQQUA supports auditing, while maintaining anonymity and confidentiality. It allows users to hold multiple accounts, perform concurrent transactions, and features a non-increasing state. AQQUA achieves auditability by introducing two authorities: one for registration and one for auditing. These authorities cannot censor financial exchanges, thus preserving the decentralized nature of the system. Users create an initial account with the registration authority and then transact with privacy by using provably unlinkable updates of it. Audits can be voluntarily initiated by the users or requested by the audit authority at any time. Compliance is proved in zero-knowledge against a set of policies which includes a maximum limit in the amount sent/received during a time period or in a single transfer, non-participation in a specific transaction or selective disclosure of the value exchanged. In order to analyze the properties of AQQUA we formally define a security model for private and auditable decentralized payment systems. Using this model, we prove that AQQUA satisfies anonymity, theft prevention, and audit soundness.

Keywords: digital payment systems, cryptocurrencies, privacy, auditability, updatable public keys

1 Introduction

Fifteen years after the introduction of Bitcoin [\[21\]](#page-17-0), the integration of blockchainbased cryptocurrencies - or more formally Distributed Payment Systems (DPS) - with the traditional financial system is still underwhelming, despite their huge popularity. This state of affairs is attributed by [\[27\]](#page-18-0) to the lack of three factors: performance, privacy, and regulation. While the lack of performance is a consequence of the underlying consensus mechanism, privacy and regulation present a deeper issue due to the inherent conflict between these two desiderata.

Regarding privacy, the inadequacy of Bitcoin's renewable pseudonyms to protect user privacy was demonstrated early on [\[20\]](#page-17-1). To overcome this problem, privacy-enhanced cryptocurrencies (e.g. Zerocash [\[4\]](#page-15-0), Monero [\[23\]](#page-17-2), Zether [\[8\]](#page-16-0), Quisquis [\[15\]](#page-16-1), Nopenena [\[1\]](#page-15-1)) arose. These systems hide transaction identities and/or amounts exchanged, thus providing privacy in a provable cryptographic manner. At the same time, however, they make it easier for malicious users to conduct illegal activities (e.g. money laundering, unauthorized funds transfer, tax evasion), thus diminishing any regulation prospects and making mainstream adoption even more unlikely.

Consequently, auditable privacy solutions [\[16,](#page-17-3) [11,](#page-16-2) [18,](#page-17-4) [19,](#page-17-5) [22,](#page-17-6) [27,](#page-18-0) [13,](#page-16-3) [2,](#page-15-2) [26,](#page-18-1) [7\]](#page-15-3) arose to make private cryptocurrencies regulation-friendly without (entirely) compromising user privacy. Financial regulations that are usually supported in such schemes are KYC (Know-Your-Customer), Anti Money Laundering (AML), as well as restrictions to the number or the value of transactions a single user can make, or to the total value that can be exchanged in a single transaction.

In this work, we address privacy and auditability through AQQUA.

Overview AQQUA equips Quisquis with auditability without changing its decentralized, permissionless, and trustless nature, while maintaining transaction anonymity and confidentiality. To this end, we introduce two new entities: A Registration Authority (RA) to enroll users into the system, and an Audit Authority (AA) to perform audits. In order to transact in AQQUA, users must first register with the RA and provide their real-world credentials, thus fulfilling KYC. Then they acquire a cryptographic pseudonym in the form of an initial updatable public key as in [\[15\]](#page-16-1), which is used to create new accounts within the system.

AQQUA accounts consist of a public key, and hiding commitments for the balance, the total amount of coins spent, and the total amount of coins received. New accounts can be created by updating the public key in a provably unlinkable manner as in [\[15\]](#page-16-1). As a result, users can own as many accounts as they wish, contrary to other private and auditable DPS. The number of accounts per user is recorded in the state of the system, which is split between two sets: the UTXOSet contains user accounts, and the UserSet maintains a mapping between a registered public key and the number of accounts that have been created by updating this public key. Of course, this number is maintained in committed form. For each new account this commitment must be updated. The addition of a new public key to the UserSet can happen only after approval by the RA. Nevertheless, the RA cannot censor or identify user transactions after enrollment.

In AQQUA, transactions can be thought of as 'wealth redistribution' between inputs and outputs, an idea from Quisquis [\[15\]](#page-16-1). Input accounts include the set of senders, the set of recipients as well as an anonymity set. Each account participating in these sets is an update of an account from the UserSet. Output accounts are new, updated but unlikable accounts for the senders, recipients, and decoys. To enforce theft prevention, the sender proves in zero-knowledge that they have correctly updated the accounts and have not taken coins away from anyone except themselves.

A user can produce a proof of compliance with a policy for a specific transaction or all their exchanges for a particular time period of interest. To do so their initial public key is required, which may be disclosed to the AA voluntarily by the user themselves, or the AA might acquire it in cooperation with the RA. Then, the user proves in zero-knowledge that they are compliant with the audited policy, using data that are only stored on-chain.

AQQUA enables voluntarily auditing, i.e. honest users may initiate the audit, in order to enjoy some advantage [\[7\]](#page-15-3). As an example, consider the case in which the AA is a cryptocurrency exchange. A user can prove to the AA that their AQQUA accounts are compliant with a policy, before being allowed to use the exchange for AQQUA coins. Another example is the case in which the user is among the set of suspects for some illicit activity, in which case honest users are able to prove their 'innocence' without giving up their privacy. On the other hand audits may be initiated by the collaboration of the AA and RA. In such cases, auditing can be effectively made mandatory if combined with off-chain penalties to non-compliant or irresponsive users.

2 Related Work

AQQUA takes the auditability route to regulation; there is an external auditor (the AA) who can request an 'explanation' of the data stored on the blockchain at will. The other option is accountability [\[9\]](#page-16-4), where policies are evaluated at the system level when certain predicates are met, and non-conforming transactions never make it to the blockchain. Auditability is better suited to the Quisquis setting, since it imposes no extra burden to its consensus layer.

Most works that combine privacy and regulation, apply to the permissioned setting [\[18,](#page-17-4) [25,](#page-17-7) [11,](#page-16-2) [13,](#page-16-3) [22,](#page-17-6) [26\]](#page-18-1), which is considered appropriate for Central Bank Digital Currencies (CBDC). These approaches use a distributed ledger to record transactions between banks or large financial organizations, which might also play the role of validators. In contrast, AQQUA makes no assumptions about its users. In order to limit the power of the validators while enforcing compliance, [\[18,](#page-17-4) [25\]](#page-17-7) use secure multi-party computation techniques to distribute the application of regulation policies between different parties. PGC [\[11\]](#page-16-2) provides a generalized design and an implementation that combines confidentiality with auditability, altogether skipping anonymity. Their proposal supports a rich set of regulation policies to limit money laundering and enable taxation. AQQUA tries to apply the expressiveness of PGC's policies to the permissionless setting, while also being anonymous to outsiders and to auditors in-between audits. UTT [\[25\]](#page-17-7) has the unique approach of allowing users a privacy budget to spend in order to satisfy KYC policies. In AQQUA, there are no limits either in spending or in the number of accounts that can be created.

In the permissionless setting, there are some works that combine auditability and privacy utilizing points of concentration like privacy mixers [\[5,](#page-15-4) [14,](#page-16-5) [7\]](#page-15-3) or exchanges [\[19\]](#page-17-5). In Haze [\[14\]](#page-16-5), compliance amounts to approving only the transactions which do not originate from a black list of banned addresses, even if the address is banned after funds were deposited on the mixer. Pisces [\[19\]](#page-17-5) achieves anonymity for all asset types that might be traded in an exchange, while supporting aggregation of statistics that allow tax calculation. Privacy pools [\[7\]](#page-15-3) allows users to prove that their withdrawals (do not) originate from (black-)

white-listed deposits. Our approach in AQQUA has two advantages over [\[5,](#page-15-4) [14,](#page-16-5) [19,](#page-17-5) [7\]](#page-15-3): Firstly, it is censorship-resistant since our authorities do not participate in transactions. Secondly, AQQUA has a global view of the blockchain, which means that compliance can be based on more complete data.

To the best of our knowledge, the closest work to AQQUA is [\[16\]](#page-17-3) which modifies the Zerocash [\[4\]](#page-15-0) coin format by adding counters that allow the data aggregation that may be used for auditing. However, [\[16\]](#page-17-3) is plagued with the same problems as Zerocash; a monotonically increasing UTXO set that affects performance which is exacerbated by the addition of auxiliary information. AQQUA inherits from Quisquis [\[15\]](#page-16-1) in which transactions don't increase the size of the UTXO set. Furthermore, in contrast to [\[16\]](#page-17-3), AQQUA does not have an option for transaction tracing, and while account information is revealed during an audit, user privacy is immediately restored afterwards.

3 Preliminaries

Notation. We denote by λ the security parameter. M is the message space of our cryptographic schemes and $V = \{0, \ldots, V\}$ defines the range of valid currency values, where V is an upper bound on the maximum possible number of coins ($|V| \ll |M|$). When an element x is sampled uniformly at random from a set X, we write $x \leftrightarrow \mathcal{X}$. Given a tuple $t = (a, b)$ we employ the dot notation, i.e. t.a or t.b and denote $t^x = (a, b)^x = (a^x, b^x)$ and $t_1 \cdot t_2 = (t_1 \cdot a \cdot t_2 \cdot a, t_1 \cdot b \cdot t_2 \cdot b)$. Our cryptographic primitives operate in a group $\mathbb G$ of prime order p generated by $g \in \mathbb{G}$ (G, p, g) where the DDH is hard, with corresponding field \mathbb{F}_p .

Updatable Public Keys. An Updatable Public Key [\[15\]](#page-16-1) (UPK) can be updated while remaining indistinguishable from freshly generated keys. We utilize the construction of [\[15\]](#page-16-1) where a public key pk_i is a tuple (g_i, g_i^{sk}) where $sk \leftarrow s \mathbb{F}_p$ is the secret key and $g_i \in \mathbb{G}$. UPKs can be updated through Update({pk_i}; r) which computes $\{pk'_i = pk_i^r\}$, $r \leftarrow s \mathbb{F}_p^*$ for all i. Using the secret key one can verify if a keypair $\mathsf{pk} = (g', h')$ is an UPK by calling VerifyKP(sk, pk) which checks if $(g')^{\rm sk} = h'$. Finally, one can use VerifyUpdate(pk', pk, r) to verify if pk' is a valid update of pk using r, by checking if $Update({p_k}; r) = pk'$. The security properties of UPKs prevent an adversary from distinguish between a new public key and an updated one (indistinguishability), and from explaining a public key update without the secret key and the randomness. We provide a formal description in Appendix [A.1.](#page-18-2)

Commitments. We use a computationally hiding, unconditionally binding, additively homomorphic (thus re-randomizable), and key anonymous commitment scheme over (\mathbb{G}, p, g) with $\boxed{m} \stackrel{\text{def}}{=} \textsf{Commit}(\mathsf{pk}, m; r) = (c, d) = (g_i^r, g^m h_i^r).$

Using UPKs as commitment public keys, one can verify and open them using the secret key, without needing to know the randomness used.

- VerifyCom(sk, pk, com, m): Verifies that com = (c, d) is a commitment to m under pk, by checking if $d = g^m c^{sk}$ holds.
- OpenCom(sk, m): Given $\boxed{m} = (c, d)$, retrieves m by calculating dc^{-sk} and brute-forcing to obtain m.

Σ-protocols. AQQUA utilizes well known Σ-protocols for proving discrete logarithm knowledge [\[24\]](#page-17-8), and DDH tuples [\[10\]](#page-16-6). We also use the variation of the Bayer-Groth shuffle proof [\[3\]](#page-15-5) from [\[15\]](#page-16-1), and Bulletproofs [\[6\]](#page-15-6) for range proofs. Furthermore, we utilize two specific Σ -protocols from [\[15\]](#page-16-1) (cf. Appendix [A.2\)](#page-19-0):

- Σ_{vu} proves the validity of a UPK update, i.e. knowledge of w: $pk' = pk^w$.
- Σ_{com} for proving that two commitments hide the same value, i.e. knowledge of $w = (v, r_1, r_2)$ such that $\mathsf{com}_1 = \mathsf{Commit}(\mathsf{pk}_1, v; r_1), \mathsf{com}_2 = \mathsf{Commit}(\mathsf{pk}_2, v; r_2)$

4 AQQUA Architecture

Entities. In AQQUA there are the following types of entities:

- Registration Authority (RA): Enrolls users by linking their real-world identity to an initial public key (pk_0) . All users' accounts within the system will originate from pk_0 , through updates. RA stores identity data off-chain for enforcement penalties on non-compliant users.
- $-$ Audit Authority (AA): Initiates audits to verify user compliance with system's policies. AA cooperates with RA to penalize non-compliant users.
- Users (U): Participants that own and transact through multiple accounts.

State. In AQQUA the state (denoted state) is composed of two sets:

- UTXOSet: Contains the 'unspent' user accounts that are outputs of valid transactions but have not yet been used as inputs.
- UserSet: Stores a mapping between the user's initial public key and a commitment to the number of accounts they own. This ensures that the user cannot withhold information from the AA during audits. While all users can update existing information in the UserSet, only the RA may add new entries.

Accounts. Users may own multiple accounts of the form $\text{act} = (\text{pk}, |\text{bl}|, |\text{out}|, |\text{in}|).$ where **bl** is the account balance and **out**, in are the total amounts the account has sent and received, respectively.

Accounts functionalities include: $\mathsf{NewAcct}(\mathsf{pk}_0; \vec{r} = (r_1, r_2, r_3, r_4)),$ which outputs a new account with an updated public key $pk = Update(pk_0; r_1)$ and zero-value commitments for balance, sent, and received amounts, using randomness r_2, r_3, r_4 respectively, VerifyAcct(acct, sk, bl, out, in), which verifies if the commitments in the account correspond to the provided values by using VerifyCom, UpdateAcct $(\{ \textsf{act}_i, \texttt{v}_{\texttt{bl}i}, \texttt{v}_{\texttt{nn}i}, \texttt{v}_{\texttt{out}i} \}_{i=1}^n; \vec{r}),$ which outputs a new set of unlinkable accounts by updating their public key and adding v_{X_i} to acct_i .

for $X \in \{bl, in, out\}$, using the homomorphic properties of the commitment scheme, and $\mathsf{VerifyUpdateAcct}(\{\mathsf{act}_i', \mathsf{acct}_i, \mathsf{v}_{\mathsf{bl}_i}, \mathsf{v}_{\mathsf{out}_i}, \mathsf{v}_{\mathsf{in}_i}\}_{i=1}^n; \vec{r}),$ which verifies if an account update was performed correctly by comparing the original and updated accounts, balances, and randomness. For the detailed formal definitions of these functionalities, see Appendix [B.1.](#page-20-0)

User information. Each user is associated with a tuple userInfo = $(\text{pk}_0, | \text{#aces})$, which is stored in the UserSet, where pk_0 represents the initial public key assigned at registration, and $\#$ accs is a commitment to the number of accounts the user owns in the UTXOSet. This commitment ensures that users cannot conceal any accounts during audits, and its opening is disclosed only to the AA.

The functionalities for user information include: GenUser() that creates a new user by producing a new key pair $(\mathsf{sk}, \mathsf{pk}_0)$, a new account for pk_0 through CreateAcct and a userInfo tuple consisting of pk_0 and a commitment to value 1, $\mathsf{VerifyUser}((\mathtt{pk}_0, \mathtt{com}), (\mathsf{sk}, \texttt{\#aces}))$ that verifies the correctness of the user information by checking if the commitment matches the number of accounts #accs using VerifyCom, UpdateUser $(\{\mathsf{userInfo}_i, \mathsf{v}_{\#accs_i}\}_{i=1}^n; r)$ that updates a set of user information tuples by modifying the commitment to reflect the updated number of accounts, VerifyUpdateUser({userInfo', user, $\mathbf{v}_{\#accs_i}\}_{i=1}^n; r$): that verifies the correctness of the updated user information by comparing the original and updated values and commitments. For the detailed formal definitions of these functionalities, see Appendix [B.2.](#page-21-0)

Policies. AQQUA supports policies that address Anti-Money Laundering (AML) requirements and selective disclosure, allowing for compliance with regulations, while preserving user privacy. We express policies as predicates over an initial public key pk_0 , a time period represented by a starting state $state_1$ and an ending state $state_2$, and auxiliary information aux specific to a compliance objective.

We introduce our supported policy predicates, where A_1, A_2 denote the sets of accounts owned by the user with pk_0 in $state_1$.UTXOSet, $state_2$.UTXOSet, respectively, and bl, out, in represent the variables acct.bl, acct.out, acct.in for a specific account acct, accordingly.

- $-$ Predicate $f_{\{\textsf{slimit}, \textsf{rlimit}\}}(\textsf{pk}_0, (\textsf{state}_1, \textsf{state}_2), \texttt{a}_{max})$ for $\textit{sending/receiving limit}$: Restricts the amount that a user can send/receive within a given time period, thus helping the enforcement of AML regulations. The sent and received amounts should not exceed a predefined threshold a_{max} , i.e.: $\sum_{\text{acct} \in A_2}$ out – amounts should not exceed a predemied threshold a_{max} , i.e., $\sum_{\text{act} \in A_2}$
 $\sum_{\text{act} \in A_1}$ out $\le a_{max}$. For f_{rlimit} we use in instead of out respectively.
- Predicate $f_{\text{txlimit}}(\text{pk}_0, (\text{state}_1, \text{state}_2), v_{\text{max}})$ for transaction value limit: Set an upper bound v_{max} to the value transferred in a single transaction, i.e.: $\sum_{\mathsf{acct} \in A_1} \mathsf{bl} - \sum_{\mathsf{acct} \in A_2} \mathsf{bl} \leq v_{\max}.$
- Predicate $f_{\sf np}({\sf pk}_0,({\sf state}_1,{\sf state}_2))$ for non-participation: Verifies that a user has not participated in any transaction during a given time period, i.e.: $(\sum_{\mathsf{acct} \in A_1} \mathsf{out} - \sum_{\mathsf{acct} \in A_2} \mathsf{out} = 0) \land (\sum_{\mathsf{acct} \in A_1} \mathsf{in} - \sum_{\mathsf{acct} \in A_2} \mathsf{in} = 0).$

 $-$ Predicate $f_{\mathsf{open}}(\mathtt{pk}_0,(\textsf{state}_1,\textsf{state}_2),v_{\mathsf{open}})$ for *open transaction*: Selective disclosure of value sent or received (v_{open}) in a specific transaction, i.e.: $(v =$ $(\sum_{\mathsf{acct} \in A_2} \mathsf{b1} - \sum_{\mathsf{acct} \in A_1} \mathsf{b1}) \in \mathcal{V}) \wedge (v = v_{\mathsf{open}} \vee v = -v_{\mathsf{open}}).$

Tracking the number of accounts a user owns is essential for enforcing valuelimit policies. Without this, users could bypass these policies by creating multiple sybil identities [\[9\]](#page-16-4). For this reason AQQUA includes an RA.

5 AQQUA Functionalities

AQQUA consists of functionalities to set up the system, register users, issue transactions and undergo audits. Registration functionalities are used to create, verify, and add registration data. Transaction functionalities are used to send funds, create and delete accounts, verify transactions and apply transactions to the state. Audit functionalities create and verify audit proofs.

5.1 Setup

The (state₀, pp) \leftarrow Setup(λ) algorithm takes as input the security parameter λ and returns the public parameters pp and the initial state state₀ which contains an empty UserSet and UTXOSet.

5.2 Registration

In order for users to register in AQQUA, they use the (sk, userInfo, acct, π) \leftarrow Register() algorithm to create an initial updatable public key pair pk_0 and the corresponding secret key sk. Using pk_0 , the algorithm creates the user's first account $\text{acct} = (\text{pk}, 0, 0, 0, 0)$, where pk is an update of pk_0 , and the corresponding userInfo = $(\mathsf{pk}_0, \boxed{1})$ entry. It also creates a NIZK argument π of correct construction, starting that both pk_0 , pk correspond to sk, that userInfo contains a commitment to 1 as the initial number of accounts, and that the acct commitments contain 0 as the initial balance, total amount sent/received.

Then, the user sends their real-world identification information along with userInfo, acct and π to the RA, which verifies them. To this end, it invokes $0/1 \leftarrow$ VerifyRegister(userInfo, acct, π , state), which first checks that the userInfo.pk₀ does not already exist in a userInfo entry of UserSet. It then executes the verification algorithm for the NIZK argument π and returns its result. If the arguments verify, the RA notifies validators for (userlated, acct, π) through an authenticated channel, so they can update the state using the state' \leftarrow ApplyRegister(userInfo, acct, state) algorithm. The algorithm adds userInfo to state.UserSet and acct to state.UTXOSet, and returns the resulting new state state'. The details are in Appendix [B.3.](#page-21-1)

5.3 Transactions

Transactions are used to exchange money and create or remove accounts.

Trans Algorithm. AQQUA's transaction algorithm extends the one in Quisquis [\[15\]](#page-16-1) by introducing additional fields to update the total amount sent from and received by each participating account.

When a user wants to send coins to one or more recipients they invoke tx \leftarrow Trans(sk, S, R, $\overrightarrow{v_s}$, $\overrightarrow{v_h}$, A). The accounts in the set S are owned by sk, while R contains the receivers. The vectors \vec{v}_s , \vec{v}_r contain the amounts to be subtracted from and added to the balance of each account in S, R, respectively. Finally, the anonymity set A is used to hide the identity of the sender and receiver accounts. The Trans algorithm which is specified in Appendix [B.4](#page-21-2) works as follows:

- Ensures that each account in S is owned by sk by using VerifyKP, and that $|S| = |\vec{v}_S|, |R| = |\vec{v}_R|.$
- $-$ Ensures that the sum of entries of \vec{v}_s , \vec{v}_R is zero, values in \vec{v}_R are positive, values in \vec{v}_s are negative, and after adding the value of \vec{v}_s to the balance of the corresponding account, the result stays non-negative (i.e. each account has enough funds to send).
- Sorts S ∪ R ∪ A in some canonical order and stores the result in inputs.
- Using UpdateAcct, re-randomizes the public keys of accounts of inputs and re-randomizes and updates their balances, total amount sent and total amount received. The balances of accounts in S are reduced by the value in the matching entry in \vec{v}_{s} and the ones in R are increased according to \vec{v}_{R} . Balances of accounts in A remain unaltered, only re-randomized. The total amount received and sent are updated appropriately, i.e. if an account is a sender/receiver account, the total amount sent/received is increased by the amount sent from/received by the account. Finally it sorts the updated accounts in some canonical order. The results are assigned to outputs.
- Forms a NIZK argument π which proves that the accounts in outputs are created with the above procedure.
- $-$ Returns tx $=$ (inputs, outputs, π).

Every account can appear in at most two transactions; once when it is created as an output and once when included in the inputs of another transaction, regardless of whether it is the actual sender or is included for anonymity only.

Create Account Algorithm. Within the system, every user can create a new account for any other registered user, which improves efficiency [\[15\]](#page-16-1). Since each account can appear only once as input in a transaction, if two concurrent transactions include the same account in their input set, one of them should be rejected. As a result, owning multiple accounts enables a user to send or receive funds by transactions created in parallel. Furthermore, increasing the number of accounts decreases the probability of including the same acount in the anonymity sets of two concurrent transactions.

The tx_{CA} = (acct, inputs, outputs, π) \leftarrow CreateAcct(userInfo, A) algorithm can be used by any user to construct a transaction that creates a new account for the owner of userInfo. It takes as input an anonymity set containing entries of UserSet, used to hide userInfo. The algorithm creates the new account $\text{acct} =$

 $(pk, 0, 0, 0, 0)$, where pk is an update of userInfo.pk₀. Using UpdateUser, it updates userInfo by increasing by one and re-randomizing the committed value for the number of accounts the user owns, and re-randomizes all commitments of entries of A. Thus, inputs = $\{$ userInfo $\}$ ∪A in some canonical order and outputs consists of the re-randomized and updated inputs. Finally, π is a NIZK argument that tx_{CA} has been constructed according to the above procedure. The detailed description of the CreateAcct algorithm is depicted in Appendix [B.5.](#page-26-0)

Delete Account Algorithm. Allowing users to delete zero-balance accounts reduces the storage overhead of AQQUA, since accounts that have no balance left might be abandoned and thus not needed to be stored in the UTXOSet. Furthermore, due to the fact that senders usually create new accounts for their intended recipients, the number of accounts in the UTXOSet increases if the option to remove zero-balance accounts is not given. Users should be incentivized to delete the zero-balance accounts they own and don't need to keep.

The tx_{DA} = (inputs, outputs, π) \leftarrow DelAcct(sk, userInfo, acct_D, acct_C, A₁, A₂) takes as input the user's secret key sk, user information userInfo, the zero-balance account to be deleted acct_D , an account acct_C to transfer the information containing the total amount sent and received of acct_D , and anonymity sets A_1, A_2 to hide $acct_D, acct_C$ and userInfo, respectively. In tx_{DA} , the set inputs consists of $A_1 \cup \{ \text{actor}_D, \text{acct}_C \}$, $A_2 \cup \{ \text{userInfo} \}$ in some canonical order. The algorithm re-randomizes and decreases by one the commitment to the number of accounts the user owns in userlnfo, adds to the corresponding fields of $\operatorname{act}_\mathsf{C}$ the total amount sent and received of acct_D and re-randomizes acct_C , removes acct_D , and re-randomizes all other accounts and user information. The set outputs consists of the resulting accounts and user information in some canonical order, and π consists of a NIZK argument of correct construction. The detailed description of the DelAcct algorithm can be found in Appendix [B.6.](#page-26-1)

Transaction Verification. The $0/1 \leftarrow$ Verify Trans(tx, state) algorithm guarantees the validity of transaction tx, which can be either transfer, create or delete account transaction. The algorithm checks that all accounts in tx.inputs are present in state and executes the verification algorithm for π .

Apply Transaction. The state' \leftarrow ApplyTrans(tx, state) algorithm is executed after the verification of the tx to update the state by adding tx.outputs and removing tx.inputs. It returns the new state state'.

Similarly to [\[15\]](#page-16-1), upon receiving a new state, users whose accounts are included in a transaction's inputs should identify their updated accounts in outputs. This can be accomplished by iterating through every acct \in outputs and using VerifyKP(sk, acct.pk). Once the user identifies an updated account, they can check whether their account was used as part of the anonymity set or as a recipient, by running VerifyCom(sk, acct.pk, acct.com_{bl}, bl), passing as input the account's previous balance bl. If the result is 1, then the account was used as

part of the anonymity set. Otherwise, the user must find out the new value for the balance. The value is small enough so that the computation of its discrete logarithm requires reasonable time.

5.4 Audit

In the audit procedure, the AA selects a user by their initial public key pk_0 , and two state snapshots $state_1, state_2$. For the policies applied to transactions (namely $f_{\text{txlimit}}, f_{\text{open}})$, state₂ should be the state that results from applying the transaction to $state_1$. For the policies applied to a time period (namely $f_{\sf slimit}, f_{\sf rlimit}, f_{\sf np}),$ the snapshots ${\sf state}_1, {\sf state}_2$ represent the beginning and end of the time period the auditor is interested in.

The user should open for each of the two snapshots the committed value of the number of accounts they own $\left(\Vert \sharp \right)$ accs field of userInfo). Then, they re-randomize and shuffle all accounts in each snapshot, and reveal their re-randomized accounts in each of the resulting snapshots' UTXOSet. For each re-randomized snapshot, they should reveal a number of accounts equal to the corresponding commitment opening. Finally, they create a NIZK argument that proves the correct re-randomization of states, the ownership of the accounts, and that the sets of re-randomized accounts satisfy the required policy predicate (cf. [section 4\)](#page-5-0).

As an example, consider a user that is audited for f_{slimit} with $\text{aux} = a_{\text{max}}$, and let $\{\text{acct}_{1i}\}_{i=1}^{\# \text{accs}_1}, \{\text{acct}_{2i}\}_{i=1}^{\# \text{accs}_2}$ be the sets of their accounts in each rerandomized snapshot. The user calculates $\boxed{\text{out}_j^*} = \prod_{i=1}^{\# \text{accs}_j} \text{act}_{ji} \boxed{\text{out}}$ for $j =$ 1, 2, and $\boxed{\text{out}^*} = \boxed{\text{out}_2^*} \left(\boxed{\text{out}_1^*} \right)^{-1}$. Notice that the value out* corresponds to the total amount sent in transactions of the user in the time period defined by state₁ and state₂. Finally, they prove in zero-knowledge that $\text{out}^* \le a_{\text{max}}$ [\[6\]](#page-15-6).

All these actions are performed in the <code>auditInfo</code> \leftarrow <code>PrepareAudit(sk, pk $_0,$ state $_1,$ </code> state₂, (f, aux)) algorithm which is invoked by the user. The algorithm returns ${\sf auditInfo} = ({\sf outputs}_1, {\sf outputs}_2, {\tt#accs}_1, \{{\sf acct}_{1i}\}_{i=1}^{{\tt#accs}_1}, {\tt#accs}_2, \{{\sf acct}_{2i}\}_{i=1}^{{\tt#accs}_2}, \pi),$ where $\texttt{outputs}_j$ is the re-randomized $\textsf{state}_j.\textsf{UTXOSet},$ for $j=1,2.$ We detail its operations in Appendix [B.7.](#page-26-2)

We note that since the user re-randomizes $\mathsf{state}_1.\mathsf{UTXOSet},\mathsf{state}_2.\mathsf{UTXOSet}$ and then discloses their accounts in the resulting sets, the AA is unable to link the disclosed accounts with the user's original accounts in the initial snapshots. This guarantees that the user's privacy is preserved during individual audits.

To check the compliance of a user with a policy, the AA executes the $0/1 \leftarrow$ ${\sf VerifyAudit}({\sf pk}_0,{\sf state}_1,{\sf state}_2,(f,{\sf aux}), {\sf auditInfo})$ algorithm, which verifies π of auditInfo and returns its result.

6 Security analysis

A private and auditable payment system should possess anonymity, theft prevention, and audit soundness in order to be secure. We formally define these properties using security games. Our adversary can corrupt users of the system, can create, delete and register new accounts, issue transactions, and request and receive audit proofs, through access to the following oracles:

- $-$ sk \leftarrow OCorrupt(pk, state): Returns the secret key for a public key of the provided state.
- state ← ORegister(): Creates a keypair and registers the public key. Returns the new state.
- $-$ (tx_{CA}, state) ← OCreateAcct(userInfo, A): Creates a new account for a userInfo entry using the anonymity set A. Returns the corresponding transaction and resulting state after the transaction application.
- $(\text{tx}_{DA}, \text{state}) \leftarrow \text{ODelAcct}(\text{userInfo}, \text{acct}_C, \text{acct}_D, A_1, A_2)$: Creates and applies a transaction to delete an account. Returns the transaction and the resulting state after the transaction application.
- (tx, state) \leftarrow OTrans(S, R, $\vec{v_s}$, $\vec{v_h}$, A): Creates and applies a transaction, returns the transaction and the new state.
- state ← OApplyTrans(tx): Checks if a transaction is valid and if so, applies it. Returns the resulting state.
- $-$ auditInfo \leftarrow OPrepareAudit $(\text{pk}_0,\text{state}_1,\text{state}_2,(f,\text{aux}))$: Creates and returns an audit proof.

Our security games make use of bookkeeping functionalities which can be called by the challenger and the available oracles. The bookkeeping keeps a list states of consecutive states created through oracle queries, a set entries containing all the secret keys that control the accounts appearing in these states, and a partition of the keys set into honest and corrupt (controlled by the adversary) keys, honest and corrupt, respectively. The bookkeeping functionalities are:

- $-$ sk \leftarrow find Secret Key(pk, state): Finds the secret key corresponding to a public key present in a state.
- $− s ← totalWeather(set, state): Returns the total amount of funds of the accounts$ of state that are owned by a set of secret keys (set $=$ honest or set $=$ corrupt).
- $-$ 0/1 \leftarrow verifyPolicy(pk_0 , state₁, state₂, (*f*, aux)): Checks whether pk_0 is compliant with policy f for the time period represented by $\mathsf{state}_1, \mathsf{state}_2.$

We provide formal descriptions in Appendix [C.1](#page-27-0) and Appendix [C.2.](#page-31-0)

6.1 Anonymity

Anonymity requires that an observer of the system cannot find the identities of senders and receivers of a transaction if they don't own the sender's private key, and that even the recipient of a transaction cannot know the sender. Anonymity is defined in Game [1](#page-11-0) and [Definition 1,](#page-11-1) where the following rules must be enforced or else the adversary could trivially guess b.

– Both senders must be honest. If one of the senders were corrupted, the adversary would be able to see whose account's balance decreases.

Game 1: Anonymity game $\text{Exp}_{\mathcal{A}}^{\text{anon}}(\lambda)$

```
Input : \lambdaOutput: \{0,1\}b \leftarrow \{0, 1\}(\mathsf{state}_0, \mathsf{pp}) \leftarrow \mathsf{Setup}(\lambda)(\mathsf{acct}_0, \mathsf{acct}_1, \mathsf{acct}'_0, \mathsf{acct}'_1, \mathtt{A}, v_0, v_1) \leftarrow\mathcal{A}^{\text{OCorrupt}, \text{ORegister}, \text{OCreatedAcct}, \text{ODelAcct}, \text{OTrans}, \text{OApplyTrans}}(\text{state}_0)state ← states[-1] // most recent state of bookkeeping
\mathsf{sk}_0 \leftarrow \mathsf{findSecretKey}(\mathsf{actor}.\mathsf{pk},\mathsf{state}); \, \mathsf{sk}_1 \leftarrow \mathsf{findSecretKey}(\mathsf{acct}_1.\mathsf{pk},\mathsf{state})\mathsf{sk}_0^i \leftarrow \mathsf{findSecretKey}(\mathsf{acct}_0'.\mathsf{pk},\mathsf{state}); \, \mathsf{sk}_1' \leftarrow \mathsf{findSecretKey}(\mathsf{acct}_1'.\mathsf{pk},\mathsf{state})\bf{if}\,\,(\rm{sk}_0\in\rm{corrupt}\vee\rm{sk}_1\in\rm{corrupt})\vee((\rm{sk}'_0\in\rm{corrupt}\vee\rm{sk}'_1\in\rm{corrupt})\wedge((\rm{acct}'_0\neq\rm{sk}'_1\in\rm{corrupt}))\mathsf{acct}_1') \vee (\mathsf{acct}_0' = \mathsf{acct}_1' \wedge v_0 \neq v_1))) \vee (\mathsf{acct}_0.\mathsf{b1} < v_0 \vee \mathsf{acct}_1.\mathsf{b1} < v_1) \mathsf{~then}return ⊥
for y \in \{0,1\} do
       A_y \leftarrow Aif sk_0 \neq sk_1 then A_y \leftarrow A \cup \{\mathsf{acct}_{1-y}\}\textbf{if } \textsf{sk}'_0 \neq \textsf{sk}'_1 \textbf{ then } \textbf{A}_y \leftarrow \texttt{A} \cup \{\textsf{acct}'_{1-y}\}\mathsf{tx}_{y} \leftarrow \mathsf{Trans}(\mathsf{sk}_y, \{\mathsf{acct}_y\}, \{\mathsf{acct}'_y\}, (-v_y), (v_y), \mathtt{A}_y)if VerifyTrans(tx<sub>y</sub>, state) = 0 then return \perpstate<sup>\prime</sup> ← ApplyTrans(tx<sub>b</sub>, state)
 b' \leftarrow \mathcal{A}(\mathsf{state}')return (b = b')
```
– Both receivers are honest. If both were corrupted then $\operatorname{acct}'_0 = \operatorname{acct}'_1$ and $v_0 = v_1$. If one is corrupted, the adversary would be able to see which account's balance increased or the amount by which it increased.

Definition 1. The advantage of the adversary in winning the anonymity game is defined as: $\mathsf{Adv}_{\mathcal{A}}^{\text{anon}}(\lambda) = \Pr[\mathsf{Exp}_{\mathcal{A}}^{\text{anon}}(\lambda) = 1] - \frac{1}{2}$ $\frac{1}{2}$ | . A DPS satisfies anonymity if for every PPT adversary A, $\text{Adv}_{\mathcal{A}}^{\text{anon}}(\lambda)$ is negligible in λ .

We formally prove that AQQUA provides anonymity, through a sequence of hybrid arguments (cf. Appendix [C.3\)](#page-31-1). Intuitively, we argue that any PPT adversary A capable of distinguishing between tx_0, tx_1 in the anonymity game (find if $b' = b$ can be used to break either the indistinguishability of the UPK scheme, the hiding property of the commitment scheme, or the zero-knowledge property of the NIZK arguments. Transactions consist of inputs, outputs, and NIZK argument π (and if the transaction is the result of CreateAcct or DelAcct a newly created account acct). One way A could determine b is based on π , but that violates the zero-knowledge property of the NIZK arguments. Another way that A could determine b is to distinguish between tx_0, tx_1 through the outputs sets of each tx. The only differences in the two outputs sets x_0 outputs, tx_1 outputs are the accounts which are used in $P = S \cup R$ and in A as well as the amount v used to increase/decrease the variables in the accounts of P. However, since both the accounts' amounts and transferred value v are presented in a committed form, if A could determine b based on the different values v_0, v_1 then the hiding

property of the commitment scheme would be violated. In addition, since all the accounts participating in the transaction are updated and randomly permuted, A cannot use P_0 , A_0 , P_1 , A_1 to distinguish the two transactions without violating the indistinguishability property of the UPK scheme.

6.2 Theft prevention

Theft prevention means that users can only move funds from accounts they own. It is formally defined in Game [2](#page-12-0) and [Definition 2.](#page-12-1) In order for the adversary to win the theft prevention game, they have to output a valid transaction that, when applied, either increases the wealth of the users they control, decreases the wealth of the honest parties, or alters the total wealth of all the users (i.e. the adversary's transaction either created or destroyed wealth).

Game 2: Theft prevention game $Exp_{\mathcal{A}}^{\text{theff}}(\lambda)$

```
Input : \lambdaOutput: \{0,1\}(\mathsf{state}_0, \mathsf{pp}) \leftarrow \mathsf{Setup}(\lambda)\mathsf{tx} \leftarrow \mathcal{A}^\mathsf{OCorrupt, ORegister, OCreated, CDelAcct, OFrans, OApply Trans}(\mathsf{state}_0)state ← states[-1] // most recent state of bookkeeping
s_h \leftarrow totalWealth(honest, state)
s_c \leftarrow totalWealth(corrupt, state)
if VerifyTrans(tx, state) = 0 then return \perpstate' \leftarrow ApplyTrans(tx, state)s'_h \leftarrow \textsf{totalWealth}(\textsf{honest},\textsf{state}')s'_c \leftarrow \textsf{totalWealth}(\textsf{corrupt},\textsf{state}')\textbf{return} \; (s_h' < s_h) \vee (s_c' > s_c) \vee (s_c' + s_h' \neq s_c + s_h)
```
Definition 2. The advantage of the adversary in winning the theft prevention game is defined as $\mathsf{Adv}_{\mathcal{A}}^{\text{theft}}(\lambda) = \Pr[\mathsf{Exp}_{\mathcal{A}}^{\text{theft}}(\lambda) = 1].$ A DPS satisfies theft prevention if for every $\Pr T$ adversary \mathcal{A} , $\operatorname{Adv}_{\mathcal{A}}^{\text{thift}}(\lambda)$ is negligible in λ .

We formally prove that AQQUA satisfies theft prevention in Appendix [C.4.](#page-36-0) Intuitively, we argue that any PPT adversary A , capable of winning the theftprevention game, can be used to break either the unforgeability property of the UPK scheme, the binding property of the commitment scheme, or the soundness property of the NIZK arguments. In order to win the theft-prevention game, A should submit a transaction tx that either increases the total balance of the corrupted users, decreases the balance of honest users, or does not maintain preservation of value. This can happen in the following ways: Firstly, if the adversary is able to transfer some amount from a honest user's account. However, this means that A can compute the sk of the honest account, thus the unforgeability property of the UPK scheme is violated. Secondly, if A manages to transfer more coins than the corrupted account holds. But in order for such a transaction to be valid, the adversary should either be able to make a NIZK argument that violates the soundness property, or to compute an opening to a commitment with balance different from the real one, hence breaking the binding property of the commitment scheme. The third way is by creating a transaction that breaks preservation of value, but in order for such a transaction to be valid, A should again be able to construct an unsound NIZK argument or break the binding property of the commitment scheme.

6.3 Audit soundness

Audit soundness means that there cannot be a successfully verified audit generated by a user who is non-compliant. Our definition in Game [3](#page-13-0) is inspired from verifiability in electronic voting [\[12\]](#page-16-7). In order for the adversary to win the audit soundness game for a policy f , they have to output a valid audit proof for a user that is non-compliant regarding the particular policy.

Definition 3. The advantage of the adversary in winning the audit soundness game for policy f is defined as: $\mathsf{Adv}_{\mathcal{A},f}^{\text{augound}}(\lambda) = \Pr[\mathsf{Exp}_{\mathcal{A},f}^{\text{augound}}(\lambda) = 1].$ A DPS satisfies audit soundness for a policy f if for every PPT adversary A , Adv $_{\mathcal{A},f}^{\text{augound}}(\lambda)$ is negligible in λ .

We formally prove that AQQUA possesses audit soundness in Appendix [C.5.](#page-38-0) Intuitively, we argue that any PPT adversary A capable of winning the audit soundness game can be used to break either the binding property of commitment scheme or the soundness property of the NIZK arguments. In order to win the the audit soundness game, A should either create a valid NIZK argument without knowing the corresponding witness, or hide some of their accounts from the AA. However, the former attack violates the soundness property of the NIZK argument. The latter requires A to be able to open their commitment | #accs to a different value, but this again breaks binding.

7 Performance

We follow the approach of Quisquis [\[15\]](#page-16-1) to reason about the performance of AQQUA. Each AQQUA account consists of 8 group elements, twice the 4 used in [\[15\]](#page-16-1), resulting in doubling the number of group elements required per transaction. Thus, AQQUA transactions contain $48n$ group elements, compared to $24n$ in [\[15\]](#page-16-1), where n represents the number of accounts in the inputs or outputs list. Using the same elliptic curve as [\[15\]](#page-16-1), with each group element requiring 33 bytes, we project that an AQQUA transaction requires 1584n bytes.

In AQQUA, the inclusion of the new variables out, in results in each proof requiring additional Σ-protocols to verify both the correct shuffling of the commitments to these values and the proper updating of these values, as described in the transaction algorithm. Specifically, to implement this, each proof uses $4n + 2|\mathbf{S}| + 2\log_2(|\mathbf{S}|) + 2\log_2(log_2(V)) + 8$ more group elements and $8n + 4|\mathbf{S}| + 9$ more field elements compared to Quisquis. Recall that the total size of the proof in Quisquis is $6n + 22\sqrt{n} + 52 + 2(\log_2(|S| + |R|) + \log_2(\log_2(V)))$ group elements and $6n + 10\sqrt{n} + 39$ field elements. Thus, asymptotically, the transaction proofs in AQQUA and Quisquis require the same size.

Regarding the audit, AQQUA requires $O(\sqrt{|\text{UTXOSet}|})$ group and field elements for shuffling. Additionally, the audit involves a constant number of group and field elements equal to the number of accounts owned by the audited user, alongside $2\log_2(\log_2(V)) + 4$ group elements and 5 field elements. The audit can be optimized by introducing a smaller anonymity set instead of the whole UTXOSet.

8 Conclusion and Future Work

In this work we presented AQQUA, a decentralized private and auditable payment system. AQQUA accounts allow the aggregation of the total influx/outflux for an updatable public key while maintaining privacy. AQQUA authorities allow checking compliance to specific policies without intervening in the normal flow of transactions. Auditing may be voluntary and follows minimal information disclosure practices. External mechanisms can be used to prevent AA from abusing its power and requesting unnecessary audits. We also formally defined and proved security for AQQUA.

This work is a first step towards a general framework for non-invasive but auditable and private cryptocurrencies. In this regard, we plan to explore applying the AQQUA architecture to other cryptocurrencies beyond Quisquis (i.e. in [\[1\]](#page-15-1)). We also plan to explore more policies that can be supported by AQQUA and to address in a game-theoretic manner the motivation of users to participate in audits. Additionally, we aim to provide ways to strengthen user privacy in relation to the size of the anonymity set and its sampling, without disregarding their effect on performance. Finally, another direction we are considering is to convert audit proofs to be designated-verifier [\[17\]](#page-17-9). As a result, the AA will be able to simulate them, and thus it will be the only entity convinced about the audit results. This may increase the privacy of the participants, but it will interfere with the trust dynamics of the system. As a result, a thorough consideration and formal modelling of the motives and actions of the AA is required.

A Building Blocks

A.1 Updatable Public Keys

AQQUA accounts are built on the Updatable Public Key (UPK) primitive from [\[15\]](#page-16-1) In a UPK scheme public keys can be updated while remaining indistinguishable from freshly generated keys.

More specifically, a UPK scheme is a tuple (Setup, KGen, Update, VerifyKP, VerifyUpdate).

- Setup generates the public parameters, which are implicitly given as input to all other algorithms, i.e. $pp \leftarrow$ Setup(λ). For instance, pp could be a prime-order group (\mathbb{G}, g, p) .
- KGen generates a keypair (pk,sk). Concretely, it is implemented as: Sample $r, \textsf{sk} \leftarrow \mathbb{F}_p$, calculate $\textsf{pk} = (g^r, g^{r\textsf{sk}})$ and output (sk, \textsf{pk}).
- Update takes as input a set of public keys $\{\mathsf{pk}_i\}_{i=1}^n$ and generates a new set $\{\mathsf{pk}_i'\}_{i=1}^n$ where $\mathsf{pk}_i' = \mathsf{pk}_i^r = (g_i^r, g_i^{r\cdot \mathsf{sk}})$ for all *i*.
- VerifyKP takes as input a keypair (sk, pk) and checks if it is valid, i.e. if pk corresponds to sk. It is constructed by parsing $pk = (g', h')$ and outputting the result of the check $(g')^{\mathsf{sk}} \stackrel{?}{=} h'.$
- VerifyUpdate takes as input a pair of public keys and some randomness $(\mathsf{pk}', \mathsf{pk}, r)$ and checks if pk' is a valid update of pk using r. This is done by checking if $Update(\mathsf{pk}; r) \stackrel{?}{=} \mathsf{pk}'.$

An UPK scheme must satisfy the properties next, formally defined in [\[15\]](#page-16-1):

- Correctness: All honestly generated keys verify correctly, the update process can be verified and the updated keys also verify successfully.
- Indistinguishability, meaning that an adversary cannot distinguish between a freshly generated public key and an updated version of a public key it already knows.

– Unforgeability, meaning that for every honestly generated keypair an adversary cannot learn the secret key of an updated public key without knowing the secret key of the original public key.

If the DDH assumption holds in (\mathbb{G}, g, p) then the construction of section [3](#page-3-0) satisfies correctness, indistinguishability and unforgeability [\[15\]](#page-16-1).

A.2 Σ-protocols

Let R be a binary relation for instances x and witnesses w, and let $\mathcal L$ be its corresponding language, i.e. $\mathcal{L} = \{x | \exists w : (x, w) \in R\}$. A $\mathcal{L}\text{-protocol for } R$ is a three-move public-coin protocol between two PPT algorithms P, V, whose transcript consists of the following phases: (1) Commit: P commits to an initial message a and sends it to $V(2)$ Challenge: V sends a challenge c to P (3) Response: P responds to the challenge with message z.

A Σ -protocol must satisfy the following properties:

- **Completeness:** if $x \in \mathcal{L}$, then if P acts according to the protocol, V always accepts the transcript.
- Special Soundness: given two transcripts with the same commitment and different challenges $(a, c, z), (a, c', z')$ one can efficient compute w such that $(x, w) \in R$.
- Special honest-verifier zero-knowledge (SHVZK): there exists a PPT simulator Sim that on input $x \in L$ and a honestly generated verifier's challenge c, outputs an accepting transcript of the form (a, c, z) with the same probability distribution as a transcript between honest P, V on input x.

Additionally we utilize the following Σ -protocols defined in [\[15\]](#page-16-1) and repeated below for convenience:

 Σ_{vu} : proof a valid update. Prover shows knowledge of w such that $pk' = pk^w$.

 $\overline{\mathbf{Prover}(\mathsf{pk}, \mathsf{pk}', w)}$ \qquad $\mathbf{Verifier}(\mathsf{pk}, \mathsf{pk}')$ $s \leftarrow \mathbb{F}_p$ $\alpha \leftarrow \mathsf{pk}^s = (g^s, h^s) \stackrel{\alpha}{\longrightarrow}$ $\xleftarrow{c} c \leftarrow \{0,1\}^{\kappa}$ $z \leftarrow cw + s$ \longrightarrow Check $pk^z = (pk')^c \cdot \alpha$

– Σ_{com} : proof of knowledge of two commitments of the same value v under different public keys. Prover shows knowledge of $w = (v, r_1, r_2)$ such that $\texttt{com}_1 = \textsf{Commit}(\textsf{pk}_1, v; r_1), \texttt{com}_2 = \textsf{Commit}(\textsf{pk}_2, v; r_2).$

 $pk_1 = (g_1, h_1), com_1 = (c_1, d_1)$ $\overline{\mathsf{pk}_2} = (g_2, h_2), \mathsf{com}_2 = (c_2, d_2)$ $Prover(v, r_1, r_2)$ Verifier $v', r'_1, r'_2 \leftarrow \mathbb{F}_p$ $(e_1, f_1) \leftarrow (g_1^{r_1'}, g^{v'} h_1^{r_1'})$ $(e_2, f_2) \leftarrow (g_2^{r'_2}, g^{v'} h_2^{r'_2})$ e_1, f_1, e_2, f_2 \xleftarrow{x} $x \leftarrow$ ₹ {0, 1}^{κ} $(z_v, z_{r_1}, z_{r_2}) \leftarrow x(v, r_1, r_2) + (v', r'_1, r'_2)$ z_v,z_{r_1} $\xrightarrow{z_v,z_{r_1},z_{r_2}}$ Check for $i = 1, 2$: $g_i^{z_{r_i}} = c_i^x \cdot e_i$ $g^{z_v}h_i^{z_{r_i}}=d_i^x\cdot f_i$

B AQQUA Components

B.1 Accounts

The following functionalities create, verify and update accounts:

- acct ← NewAcct(pk₀; r_1, r_2, r_3, r_4): takes as input a public key pk₀ and outputs a new account of the form $\text{acct} = (\text{pk}, \boxed{\text{bl}}, \boxed{\text{out}}, \boxed{\text{in}})$, where $\text{pk} =$ $\mathsf{Update}(\mathrm{pk}_0; r_1), \ \boxed{\mathtt{bl}} = \mathsf{Commit}(\mathtt{pk}, 0; r_2), \ \boxed{\mathtt{out}} = \mathsf{Commit}(\mathtt{pk}, 0; r_3) \ \ \text{and}$ $\vert \text{in} \vert = \text{Commit}(\text{pk}, 0; r_4).$
- $-0/1 \leftarrow$ VerifyAcct(acct, sk, bl, out, in): Parses acct as (pk, com₁, com₂, com₃) and outputs 1 if

VerifyKP(sk, pk) ∧ VerifyCom(sk, pk, com₁, b1)∧ VerifyCom(sk, pk, com₂, out) ∧ VerifyCom(sk, pk, com₃, in)∧ $(b1, out, in \in \mathcal{V})$

 $-$ {acct'_i} $_{i=1}^n \leftarrow \mathsf{UpdateAcct}(\{\mathsf{act}_i, \mathtt{v}_{\mathtt{bl}i}, \mathtt{v}_{\mathtt{out}i}, \mathtt{v}_{\mathtt{in}i}\}_{i=1}^n; r_1, r_2, r_3, r_4)$ takes as input a set of accounts $\text{acct}_i = (\text{pk}_i, \text{com}_{\text{bl}}; \text{com}_{\text{out}}; \text{com}_{\text{in}})$ and values $|\mathbf{v}_{\text{bl}}|, \mathbf{v}_{\text{out}}|, \mathbf{v}_{\text{in}} \in \mathcal{V}$ and outputs a new set of accounts $\{\text{acct}'_i\}_{i=1}^n$, where

 $\mathsf{acct}_i' \leftarrow (\mathsf{Update}(\mathsf{pk}_i; r_1), \mathsf{com}_{\mathsf{bl}_i} \; \odot \mathsf{Commit}(\mathsf{pk}_i, \mathtt{v}_{\mathsf{bl}_i}; r_2),$ $\mathsf{com}_{{\mathsf{out}}_i} \: \odot \: \mathsf{Commit}({\sf pk}_i, {\tt v}_{{\mathsf{out}}_i}; r_3), \mathsf{com}_{{\mathsf{in}}_i} \: \odot \: \mathsf{Commit}({\sf pk}_i, {\tt v}_{{\mathsf{in}}_i}; r_4)).$

 $-0/1 \leftarrow$ Verify $\sf{UpdateAcct}(\{ \mathsf{acct}_i', \mathsf{acct}_i, v_{\texttt{bl}i}, v_{\texttt{out}i}, v_{\texttt{in}i} \}_{i=1}^n; r_1, r_2, r_3, r_4)$: outputs 1 if

 $\{{\sf acct}_i'\}_{i=1}^n = {\sf UpdateAcct}(\{{\sf acct}_i, {\tt v_{b1}}_i, {\tt v_{out}}_i, {\tt v_{in}}_i\}_{i=1}^n; r_1, r_2, r_3, r_4) \land (|{\tt v_{b1}}|, {\tt v_{out}}, {\tt v_{in}} \in \mathcal{V}).$

B.2 User Information

The following functions create, verify and update userInfo entries of the UserSet.

- $-$ (sk, userInfo, acct) \leftarrow GenUser(): Picks $r_1, r_2, r_3, r_4, r_5 \leftrightarrow \mathbb{F}_p^*$ and let \vec{r} = (r_1, r_2, r_3, r_4) . Then runs $(\mathsf{sk}, \mathsf{pk}_0) \leftarrow \mathsf{KGen}(0)$, acct $\leftarrow \mathsf{NewAcct}(\mathsf{pk}_0; \vec{r})$, calculates the tuple **userInfo** = $(\text{pk}_0, \text{Commit}(\text{pk}_0, 1; r_5))$ and returns (sk, **userInfo**, acct). $\,0/1$ \leftarrow VerifyUser((p $\rm k_{0},$ com), (sk, #accs)): $\rm outputs$ 1 if VerifyUpdate(sk, p $\rm k_{0})$ \wedge
- $\mathsf{VerifyCom}(\mathsf{sk},\mathrm{pk}_0,\mathsf{com},\mathsf{\#acos}) \wedge (\mathsf{\#aces} \in \mathcal{V})$
- $-$ {userInfo $_i^{\prime}\}_{i=1}^n \leftarrow$ UpdateUser $(\{\mathsf{userInfo}_i, \mathsf{v}_{\#accs_i}\}_{i=1}^n; r)$ takes as input a set of user-value pairs, where $\mathsf{userInfo}_i = (\mathsf{pk}_{0i}, \mathsf{com}_{\# \mathsf{accs}_i})$ and $\mathsf{v}_{\# \mathsf{accs}_i} \in \mathcal{V}$, and outputs a new set of users $\{\text{userInfo}'_i\}_{i=1}^n = \{(\text{pk}_{0i}, \text{com}_{\text{#accs}'_i})\}_{i=1}^n$ where

 $\mathrm{com}^\prime_{\# \mathrm{accs} i} = \mathrm{com}_{\# \mathrm{accs} i} \odot \mathrm{Commit}(\mathrm{pk}_0, \mathrm{v}_{\# \mathrm{accs}}; r)$

 $-$ 0/1 \leftarrow VerifyUpdateUser({userInfo $'_i$, user $_i$, v $_{\#accs}$ } $_{i=1}^n$; $r)$ outputs 1 if

 $\{{\sf userInfo'}\}_{i=1}^n = {\sf UpdateUser}(\{{\sf userInfo}_i, {\tt v}_{\#accs_i}\}_{i=1}^n; r) \wedge ({\tt v}_{\#accs} \in \mathcal{V})$

B.3 Registration Algorithm

The registration algorithm is depicted in [Figure 1.](#page-21-3)

The Register algorithm performs the following steps: 1. Run (sk, userInfo, acct) \leftarrow GenUser(). 2. Create a NIZK argument π of the relation $R(x, w)$, where $x = (\text{act}, \text{userInfo})$, $w =$ (sk) and $R(x, w) = 1$ if: $\mathsf{VerifyCom}({\sf userInfo}.{\sf pk}_0,{\sf userInfo}.\mathtt{com}_{\# {\sf access}},({\sf sk},1)) = 1$ \wedge VerifyKP(userInfo.p $\mathrm{k}_0,$ sk) $=1$ \wedge VerifyAcct(acct, sk, $0, 0, 0) = 1$ 3. Return (sk, userInfo, acct, π).

Fig. 1. The Register algorithm.

B.4 Transaction Algorithm

The detailed description of the Trans algorithm appears in [Figure 2.](#page-22-0) The algorithm takes as input the sender's secret key sk, the set of sender accounts S, the set of receiver accounts R, two vectors $\overrightarrow{v_s}, \overrightarrow{v_R}$ containing the desired changes to the balances of the sender and receiver accounts respectively, and an anonymity set A. It returns a transaction $tx = (inputs, outputs, \pi)$, where π is a NIZK argument that outputs is created correctly.

The algorithm $tx \leftarrow$ Trans(sk, S, R, $\vec{v_s}$, $\vec{v_s}$, A) performs the following steps:

- 1. Ensure that for each $\text{acct} \in S$, $\text{VerifyKP}(\text{sk}, \text{acct}, \text{pk}) = 1$, and that $|S| = |\vec{v_s}|, |R| =$ $\frac{1}{|\vec{v_R}|}$.
- 2. Let $I_s = \{1, ..., |S|\}$. For all $i \in I_s$, calculate the opening of the committed balance $\boxed{\text{bl}_i}$ of acct_i \in S, denoted bl_i .
- 3. Let $\overrightarrow{v_{b1}} = \overrightarrow{v_s} || \overrightarrow{v_k}$, where || denotes vector concatenation. Let also $I_R = { |S| +}$ $1, \ldots, |S| + |R|$. Ensure that:
	- (a) $\sum_{i\in I_{\texttt{S}}\cup I_{\texttt{R}}} \mathbf{v}_{\texttt{bl}} = 0$
	- (b) $\forall i \in I_R : \mathbf{v}_{\text{bl}_i} \in \mathcal{V}$
	- (c) $\forall i \in I_{\text{S}} : -\mathbf{v}_{\text{bl}_i} \in \mathcal{V} \wedge \mathbf{bl}_i + \mathbf{v}_{\text{bl}_i} \in \mathcal{V}$
- 4. Construct $\overrightarrow{v_{\text{out}}}$, $\overrightarrow{v_{\text{in}}}$ as follows:

(a)
$$
\overrightarrow{v_{out}} = \overrightarrow{v_s} || (0, \ldots, 0) || (0, \ldots, 0)
$$

\n
$$
\overrightarrow{v_{in}} = \underbrace{(0, \ldots, 0)}_{\text{length } |S|} || \overrightarrow{v_R} || (0, \ldots, 0).
$$
\n(b) $\overrightarrow{v_{in}} = \underbrace{(0, \ldots, 0)}_{\text{length } |S|} || \overrightarrow{v_R} || (0, \ldots, 0).$

Furthermore, expand $\overrightarrow{v_{b1}}$ too with zero values for each acct \in A.

- 5. Sort P ∪ A in some canonical order and stores the result in inputs. Let also $\overrightarrow{v_{\text{bl}}}, \overrightarrow{v_{\text{out}}}, \overrightarrow{v_{\text{in}}}$ be the permutation of $\overrightarrow{v_{\text{bl}}}, \overrightarrow{v_{\text{out}}}, \overrightarrow{v_{\text{in}}}$ in the same order. Let I_s^s, I_h^s, I_h^s denote the indices of the respective accounts of the sender, the recipients and the anonymity set in this list.
- 6. Pick $r_1, r_2, r_3, r_4 \leftarrow \mathbb{F}_p^*$ and let $\vec{r} = (r_1, r_2, r_3, r_4)$. Perform UpdateAcct(inputs, $\overline{v_{bl}}'$, $\overline{v_{out}}'$, $\overline{v_{in}'}$; \overrightarrow{r}) and sort the result in some canonical order. The results are assigned to outputs.
- 7. Let $\psi: \{1,...,n\} \rightarrow \{1,...,n\}$ be the implicit permutation mapping inputs into outputs; such that accounts $\text{acct}_i \in \text{inputs}$ and $\text{acct}'_{\psi(i)} \in \text{outputs share the}$ same secret key.
- 8. Form a NIZK argument π of the relation $R(x, w)$, where x (inputs, outputs), $w = (\text{sk}, {\{\text{bl}_i, \text{out}_i, \text{in}_i\}}_{i \in I_s^*}, \overline{\text{v}_{\text{bl}}'}, \overline{\text{v}_{\text{out}}'}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{\text{in}}}, \overline{\text{v}_{$ and $R(x, w) = 1$ if

 $\mathsf{VerifyUpdateAcct}(\mathsf{acct'}_{\psi(i)}, \mathsf{acct}_i, 0, 0, 0; \overrightarrow{r}) = 1 \,\, \forall i \in \mathtt{I}_\mathtt{A}^*$

 \wedge $(\mathsf{VerifyUpdateAcct}^\prime_{\psi(i)}, \mathsf{act}_i, \mathsf{v_{\textrm{bl}}}_i^\prime, \mathsf{v_{\textrm{out}}}_i^\prime, \overrightarrow{r}) = 1 \wedge \mathsf{v_{\textrm{bl}}}_i^\prime, \mathsf{v_{\textrm{out}}}_i^\prime, \mathsf{v_{\textrm{in}}}_i^\prime \in \mathcal{V}) \ \forall i \in \textrm{I}_\textrm{R}^*$ \wedge VerifyUpdateAcct $(\mathrm{acct}'_{\psi(i)}, \mathrm{acct}_i, \mathrm{v_{\mathrm{b}}}_i', \mathrm{v_{\mathrm{out}}}_i', \mathrm{v_{\mathrm{in}}}_i'; \overrightarrow{r}) = 1 \; \forall i \in \mathrm{I}_\mathrm{S}^*$

 \wedge VerifyAcct $(\mathsf{acct}'_{\ \psi(i)},\mathsf{sk},\mathsf{bl}_i+v_{\mathsf{bl} i}',\mathsf{out}_i+v_{\mathsf{out} i}',\mathsf{in}_i+v_{\mathsf{in} i}')=1 \ \forall i\in \mathtt{I}_\mathtt{S}^*$

$$
\begin{aligned} \wedge \sum_{i \in \mathtt{I}^*_\mathtt{S} \cup \mathtt{I}^*_\mathtt{R} \cup \mathtt{I}^*_\mathtt{A}} \mathtt{v_{\text{b1}}}_i' &= 0 \\ \wedge -\mathtt{v_{\text{b1}}}_i' &= \mathtt{v_{\text{out}}}_i' \ \forall i \in \mathtt{I}^*_\mathtt{S} \\ \wedge \mathtt{v_{\text{b1}}}_i' &= \mathtt{v_{\text{in}}}_i' \ \forall i \in \mathtt{I}^*_\mathtt{R} \\ \wedge \mathtt{v_{\text{out}}}_i' &= \mathtt{v_{\text{in}}}_i' &= 0 \ \forall i \in \mathtt{I}^*_\mathtt{A} \end{aligned}
$$

The transaction created is $tx = (inputs, outputs, \pi)$.

Fig. 2. The Trans algorithm.

Proof of transaction correctness In each transaction created from Trans algorithm a prover essentially has to prove in zero-knowledge that:

- 1. accounts in outputs are proper updates of inputs
- 2. the updates of balances satisfy preservation of value
- 3. balances in accounts of recipients and anonymity set do not decrease
- 4. the sender account in outputs contain a balance in V
- 5. the sender account in outputs contain a balance in γ .
5. the vectors $-\overline{v_{b1}}'$, $\overline{v_{out}}'$ have the same values for the sender accounts and $\overrightarrow{v_{\text{bl}}}, \overrightarrow{v_{\text{out}}}$ have the same values for the sender accounts and $\overrightarrow{v_{\text{bl}}}, \overrightarrow{v_{\text{in}}}, \$ rest.

The properties 3,4 can be proved by range proofs - i.e. with Bulletproofs [\[6\]](#page-15-6). For the properties 1,2,5 similarly to Quisquis[\[15\]](#page-16-1) it holds that:.

Let the sender's accounts be $inputs_1, \ldots, inputs_s$ and the receivers' accounts be $\texttt{inputs}_{s+1}, \ldots, \texttt{inputs}_{t}.$ In order to easily verify the validity of the updates, the prover creates accounts $\arctan{\delta}$, where $\arctan{\delta}$, $= (\mathsf{pk}_i, \boxed{\mathsf{v}_{\texttt{bl}}}, \boxed{\mathsf{v}_{\texttt{ol}}}, \boxed{\mathsf{v}_{\texttt{in}}})$.

Since the sender-prover knows all the values of the acct_{δ} , they can create commitments for the same values under a different public key $\mathsf{pk}_{\epsilon} = (g, h)$, where $h =$ $g^{\mathsf{sk}_{\epsilon}}$. So the prover creates \textsf{acct}_{ϵ} where $\textsf{acct}_{\epsilon i} = ((g, h), \boxed{\mathsf{v}_{\texttt{bl}}_i}_{\epsilon}, \boxed{\mathsf{v}_{\texttt{out}}_i}_{\epsilon}, \boxed{\mathsf{v}_{\texttt{in}}_i}_{\epsilon})$. Then they use the homomorphic property of the commitment in order to prove the preservation of value, since $\sum_i v_{b1i} = 0 \iff \prod_i \boxed{v_{b1i}}_e$ is a commitment of 0 under $\mathsf{pk}_{\epsilon} = (g, h)$. The values in $\mathsf{acct}_{\epsilon,s+1}, \ldots, \mathsf{acct}_{\epsilon,t}$ will be used to prove that balances of recipients set and anonymity set is not decreased, meaning $v_{\text{bl}_{\epsilon,s+1}}, \ldots, v_{\text{bl}_{\epsilon,n}} \in \mathcal{V}$. In addition, in order to prove property 5, the prover shows that for $\operatorname{act}_{\epsilon,1}, \ldots, \operatorname{act}_{\epsilon,s}$ the values under the $\boxed{v_{\text{bl}_i}}_{\epsilon}$ and $\boxed{v_{\text{out}_i}}_{\epsilon}$ are the opposite. Respectively for the recipients, for $\mathrm{acct}_{\epsilon,s+1}, \ldots, \mathrm{acct}_{\epsilon,t}$ the values under the $\boxed{\mathbf{v}_{\texttt{bl}i}}_{\epsilon}$ and $\boxed{\mathbf{v}_{\texttt{in}i}}_{\epsilon}$ are the same.

Now in order to hide the sender's and the receiver's position in inputs and outputs we first shuffle inputs list to inputs′ before the updates, then we execute the updates to produce outputs′ , and finally we shuffle again after the updates to get outputs in arbitrary order. The first shuffle uses the aforementioned permutation where senders' accounts are first,followed by recipients' accounts and then the anonymity set. The second shuffle uses a permutation in order to order the outputs lexicographically.

Therefore, we need some auxiliary functions for the proof that are defined as following:

- $-$ CreateDelta $(\{\text{act}_i\}_{i=1}^n, \{v_{\text{bl}}_i\}_{i=1}^n, \{v_{\text{out}}_i\}_{i=1}^n, \{v_{\text{in}}_i\}_{i=1}^n)$: Creates a set of accounts that contains the differences between accounts' variables bl, out, in in the input and output accounts, and another set of accounts that also contains these differences but all with the global public key (q, h) :
	- 1. Parse $\texttt{acct}_i = (\mathsf{pk}_i, \texttt{com}_{\texttt{bl},i}, \texttt{com}_{\texttt{out},i}, \texttt{com}_{\texttt{in},i})$. $\text{Sample } r_{(\texttt{bl}|\texttt{out}|\texttt{in}),1}, \ldots, r_{(\texttt{bl}|\texttt{out}|\texttt{in}),n-1} \leftarrow$ \mathbb{F}_p and set $r_{(\text{bl}|\text{out}|\text{in}),n} = -\sum_{i=1}^{n-1} r_{(\text{bl}|\text{out}|\text{in}),i}.$
	- 2. Set $\mathrm{acct}_{\delta,i} = (\mathsf{pk}_i, \mathsf{Commit}(\mathsf{pk}_i, \mathrm{v}_{\texttt{bl}:i}; r_{\texttt{bl},i}), \mathsf{Commit}(\mathsf{pk}_i, \mathrm{v}_{\texttt{out}:i}; r_{\texttt{out},i}), \mathsf{Commit}(\mathsf{pk}_i, \mathrm{v}_{\texttt{in}:i}; r_{\texttt{in},i}))$
	- 3. Set $\mathrm{act}_{\epsilon,i}=((g,h),\mathrm{Commit}((g,h),{\mathtt{v}}_{\mathtt{bl}:i};r_{\mathtt{bl},i}),\mathrm{Commit}((g,h),{\mathtt{v}}_{\mathtt{out}:i};r_{\mathtt{out},i}),\mathrm{Commit}((g,h),{\mathtt{v}}_{\mathtt{in}:i};r_{\mathtt{in},i}))$
	- 4. Output $(\{\mathsf{acct}_{\delta,i}\}_{i=1}^n, \{\mathsf{acct}_{\epsilon,i}\}_{i=1}^n, \vec{r_{\mathsf{b}1}}, \vec{r_{\mathsf{out}}}, \vec{r_{\mathsf{in}}})$
- $-$ VerifyDelta $(\{\textsf{act}_{\delta,i}\}_{i=1}^n, \{\textsf{act}_{\epsilon,i}\}_{i=1}^n, \vec{v_{\texttt{DL}}}$, $\vec{v_{\texttt{out}}}$, $\vec{v_{\texttt{int}}}$, $\vec{r_{\texttt{DL}}}$, $\vec{r_{\texttt{out}}}$, $\vec{r_{\texttt{int}}}$): Verifies that accounts created using CreateDelta are consistent:
	- 1. Parse $\text{acct}_{\delta,i} = (\text{pk}_i, \boxed{v_{\text{bl}}_i}, \boxed{v_{\text{out}}_i}, \boxed{v_{\text{in}}_i}).$ 2. If $\prod_{i=1}^n \text{act}_{\epsilon,i}$, $\overline{v_{b1}} = (1, 1)$ and $\overline{\forall i}$ $\overline{v_{b1}} = \text{Commit}(pk_i, v_{b1}i; r_{b1}i)$ \wedge $\overline{\mathbf{v_{out}}_i}$ = $\mathsf{Commit}(\mathsf{pk}_i, \mathbf{v_{out}}; r_{\mathsf{out}, i}) \ \wedge \ \overline{|\mathbf{v_{in}}_i|} = \mathsf{Commit}(\mathsf{pk}_i, \mathbf{v_{in}}; r_{\mathsf{in}, i})$ \wedge VerifyAcct(acct_{e,i}, sk_e, v_{bli}, v_{outi}, v_{ini}) output 1. Else output 0.
- VerifyNonNegative($\text{acct}_{\epsilon}, v, r$): Verifies that an account contains a balances in V. More specifically, if $\text{acct}_{\epsilon}.\textsf{pk} = (g, h) \wedge \text{acct}_{\epsilon}.\overline{|\mathbf{v}_{\texttt{bl}}|} = (g^r, g^v h^r) \wedge v \in \mathcal{V}$ outputs 1. Else output 0.
- $-$ UpdateDelta $(\{\mathsf{acct}_i\}_{i=1}^n, \{\mathsf{acct}_{\delta,i}\}_{i=1}^n)$: Updates the input accounts by $\mathtt{v_{bl}}_i, \mathtt{v_{out}}_i, \mathtt{v_{in}}_i$ but with the public key unchanged:
	- 1. Parse $\texttt{acct}_i = (\texttt{pk}_i, \texttt{com}_{\texttt{bl}, i}, \texttt{com}_{\texttt{out}, i}, \texttt{com}_{\texttt{in}, i})$ and $\texttt{acct}_{\delta, i} = (\texttt{pk}'_i, \boxed{v_{\texttt{bl}}_i}, \boxed{v_{\texttt{out}}_i}, \boxed{v_{\texttt{in}}_i}$.
	- 2. If $pk_i = pk'_i \forall i$ output $\{ (pk_i, com_{b1,i} \cdot \boxed{v_{b1i}}, com_{out,i} \cdot \boxed{v_{outi}}, com_{in,i} \cdot \boxed{v_{outi}} \}$ $\overline{v_{\text{in }i}}\$, else output ⊥.
- $-$ VerifyUD(acct, acct', acct_{δ}): Verifies that UpdateDelta was performed correctly:
	- 1. Parse $\texttt{acct} = (\texttt{pk}, \texttt{com}_{\texttt{bl}}, \texttt{com}_{\texttt{out}}, \texttt{com}_{\texttt{in}}), \texttt{acct}' = (\texttt{pk}, \texttt{com}_{\texttt{bl}}', \texttt{com}_{\texttt{out}}', \texttt{com}_{\texttt{in}}')$ and $\text{acct}_\delta = (\text{pk}_\delta, \boxed{v_{\text{bl}}}, \boxed{v_{\text{out}}}, \boxed{v_{\text{in}}}$).
	- 2. Check that $pk = pk' = pk_\delta \wedge \text{com}'_{b1} = \text{com}_{b1} \cdot \boxed{v_{b1}} \wedge \text{com}'_{out}$ $com_{out} \cdot \boxed{v_{out}} \ \wedge \ com'_{in} = com_{in} \cdot \boxed{v_{in}}.$
- VerifyDeltaSender(acct_c, $v, r_{\text{bl}}, r_{\text{out}}$): Verifies that sender's value out is correct.
	- 1. Parse $\mathrm{acct}_{\epsilon} = ((g, h), [\overline{v_{\text{bl}}}_{\epsilon}, \overline{v_{\text{out}}}_{\epsilon}, \overline{v_{\text{in}}}_{\epsilon}).$
	- 2. If $\boxed{v_{b1}}_{\epsilon}$ = Commit $((g, h), -v; r_{b1}) \wedge \boxed{v_{out}}_{\epsilon}$ = Commit $((g, h), v; r_{out})$ then return 1. Else return 0.
- VerifyDeltaReceiver($\text{acct}_{\epsilon}, v, r_{\text{bl}}, r_{\text{in}}$): Verifies that receiver's value in is correct.
	- 1. Parse $\mathrm{acct}_{\epsilon} = ((g, h), [\overline{v_{\text{bl}}}_{\epsilon}, \overline{v_{\text{out}}}_{\epsilon}, \overline{v_{\text{in}}}_{\epsilon}).$
	- 2. If $\boxed{v_{b1}}_{\epsilon}$ = Commit $((g,h), v; r_{b1}) \wedge \boxed{v_{in}}_{\epsilon}$ = Commit $((g,h), v; r_{in})$ then return 1. Else return 0

Then the NIZK.Prove_{Trans} (x, w) performs the following steps:

- 1. Parse $x = (\text{inputs}, \text{outputs}), w = (\text{sk}, \{\text{bl}_i, \text{out}_i, \text{in}_i\}_{i \in I_s^*}, \overrightarrow{v_{\text{bl}}}, \overrightarrow{v_{\text{out}}}, \overrightarrow{v_{\text{in}}}, \overrightarrow{r}, \psi, I_s^*, I_h^*, I_h^*).$ If $R(x, w) = 0$ abort;
- 2. Let ψ_1 be a permutation such that $\psi_1(\mathbf{I}_\mathbf{S}^*) = [1, s], \psi_1(\mathbf{I}_\mathbf{R}^*) = [s + 1, t]$ and $\psi_1(\mathbf{I}_{\mathbf{A}}^*) = [t+1, n];$
- 3. Sample $\rho_1, \rho_2, \rho_3, \rho_4 \leftarrow \mathbb{F}_p$ and let $\vec{\rho} = (\rho_1, \rho_2, \rho_3, \rho_4);$
- 4. Set $\mathtt{inputs}' = \mathsf{UpdateAcct}(\{\mathtt{inputs}_{\psi_1(i)}, 0, 0, 0\}_i; \vec{\rho});$
- 5. Set vectors $\overrightarrow{v_{b1}}, \overrightarrow{v_{out}}, \overrightarrow{v_{in}}$ such that $v_{b1i} = v_{b1}'_{\psi(i)}, v_{outi} = v_{out}'_{\psi(i)}, v_{ini} = v_{out}'$ $v_{in}^{\prime}{}_{\psi(i)}^{\prime}$
- 6. Set $(\{\mathsf{actor}_{\delta,i}\}, \{\mathsf{actor}_{\epsilon,i}\}, r_\mathbf{bl}, r_\mathbf{out}, r_\mathbf{in}) \leftrightarrow \mathsf{CreateDelta}(\mathsf{inputs}', \overrightarrow{v_\mathbf{bl}}, \overrightarrow{v_\mathbf{out}}, \overrightarrow{v_\mathbf{ih}});$
- 7. Update outputs' \leftarrow UpdateDelta(inputs', {acct $_{\delta,i}$ });
- 8. Let $\psi_2 = \psi_1^{-1} \circ \psi, \rho_1' = \frac{r_1}{\rho_1}, \vec{\rho_2'} = \frac{r_2 \rho_2}{\rho_1} r_{\text{bl};i}, \vec{\rho_3'} = \frac{r_3 \rho_3}{\rho_1} r_{\text{out};i}, \vec{\rho_4'} =$ $\frac{r_4-\rho_4}{\rho_1}-r_{\text{in}i}$ and let $\vec{\rho'}=(\rho'_1,\vec{\rho'_2},\vec{\rho'_3},\vec{\rho'_4}).$
- 9. Update outputs $=\mathsf{UpdateAcct}(\{\mathsf{outputs}_{\psi_2(i)}, 0, 0, 0\}_i; \vec{\rho'})$
- 10. Generate a ZK proof $\pi = (\text{inputs}', \text{outputs}', \text{acts}_\delta, \text{act}_\epsilon, \pi_1, \pi_2, \pi_3)$ for the relation $R_1 \wedge R_2 \wedge R_3$ where:

 $R_1 = \{(\texttt{inputs}, \texttt{inputs}', (\psi_1, \vec{\rho}))|$ $\mathsf{VerifyUpdateAcct}(\{\mathsf{inputs}_i', \mathsf{inputs}_{\psi_1(i)}, 0, 0, 0\}_i; \vec{\rho}) = 1\},$ $R_2 = \{((\texttt{inputs}',\texttt{outputs}',\texttt{acci}_{\delta},\texttt{act}_{\delta}),(\textsf{sk},\{\texttt{bl},\texttt{out},\texttt{in}\}_{i=0}^s,\overrightarrow{v_{\texttt{bl}}},\overrightarrow{v_{\texttt{out}}},\overrightarrow{v_{\texttt{in}}},\overrightarrow{r_{\texttt{in}}},\overrightarrow{r_{\texttt{in}}}))|$ $\mathsf{VerifyUD}(\mathsf{inputs}_i', \mathsf{outputs}_i', \mathsf{acct}_{\delta,i}) = 1 \,\, \forall i$ \land VerifyUpdateAcct $(\texttt{inputs}_i', \texttt{outputs}_i', 0, 0, 0; 1, r_{\texttt{bl},i}, r_{\texttt{out},i}, r_{\texttt{in},i}) = 1 \; \forall i \in [t+1, n]$ \wedge VerifyNonNegative $(\mathsf{acct}_{\epsilon,i},\mathsf{v}_{\texttt{bl}i},r_{\texttt{bl},i}) = 1 \,\, \forall i \in [s+1,t]$ \land VerifyAcct(outputs'_i, (sk, b1_i + v_{b1i})) = 1 $\forall i \in [1, s]$ \wedge VerifyDelta $(\{ {\sf acct}_{\delta,i} \}, \{ {\sf acct}_{\epsilon,i} \}, \overrightarrow{v_{\sf bl}}, \overrightarrow{v_{\sf ub}}, \overrightarrow{v_{\sf out}}, \overrightarrow{v_{\sf ih}}, r_{\sf bit}, r_{\sf int}) = 1$ \wedge VerifyDeltaSender $(\mathsf{acct}_{\epsilon,i}, \mathtt{v}_{\mathtt{out}i}, r_{\mathtt{bl},i}, r_{\mathtt{out},i}) = 1 \; \forall i \in [1, s]$ \wedge VerifyDeltaReceiver $(\text{act}_{\epsilon,i}, \text{v}_{\texttt{bl}i}, r_{\texttt{bl},i}, r_{\texttt{in},i}) = 1 \ \forall i \in [s+1, t] \},$

 $R_3 = \{(\texttt{outputs}',\texttt{outputs},(\psi_2,\vec{\rho'}))|$

 $\mathsf{VerifyUpdateAcct}(\{\mathsf{outputs}_i, \mathsf{outputs}_{\psi_1(2)}, 0, 0, 0\}_i; \vec{\rho'}) = 1\}$

Now R_1, R_3 can be proven using a slight modification of the Bayer-Groth shuffle argument [\[3\]](#page-15-5). The Σ_2 protocol that proves R_2 consists of the following sub-protocols:

- 1. Σ_{vu} : trivial check of VerifyUD.
- 2. Σ_{δ} : prover shows knowledge of $\overrightarrow{v_{b1}}, \overrightarrow{v_{out}}, \overrightarrow{v_{in}}, r_{\text{in}}$, r_{out} , r_{in} such that $\text{VerifyDelta}(\{\text{act}_{\delta,i}\}_{i=1}^n, \{\text{act}_{\epsilon,i}\}_{i=1}^n, \overline{v_{\text{bl}}}, \overline{v_{\text{out}}}, \overline{v_{\text{int}}}, \overline{v_{\text{bit}}}, \overline{r_{\text{tot}}}$, $\overline{r_{\text{in}}}$, $\overline{r_{\text{in}}}$, $\overline{r_{\text{in}}}$, $\overline{r_{\text{in}}}$, $\overline{r_{\text{in}}}$ Σ_{δ} can be implemented by using Σ_{com} : $\varSigma_{\delta} = \wedge_{i=1}^n \varSigma_{com}((\mathsf{pk}_{\delta,i},\boxed{\mathtt{bl}}_{\delta,i}),(\mathsf{pk}_{\epsilon,i},\boxed{\mathtt{bl}}_{\epsilon,i});(\mathtt{v}_{\mathtt{bl}},r_{\mathtt{bl},i},r_{\mathtt{bl},i}))$ $\wedge_{i=1}^n\varSigma_{com}((\mathsf{pk}_{\delta,i},\fbox{\overline{out}}_{\delta,i}),(\mathsf{pk}_{\epsilon,i},\fbox{\overline{out}}_{\epsilon,i});(\mathsf{v}_{\mathsf{out}},r_{\mathsf{out},i},r_{\mathsf{out},i}))$ $\wedge_{i=1}^n \Sigma_{com}((\mathsf{pk}_{\delta,i},\boxed{\mathtt{in}}_{\delta,i}),(\mathsf{pk}_{\epsilon,i},\boxed{\mathtt{in}}_{\epsilon,i});(\mathsf{v}_{\mathtt{in}},r_{\mathtt{in},i},r_{\mathtt{in},i}))$, but the verifier additionally checks that $\forall i \mathsf{pk}_{\epsilon,i} = (g,h)$ and that $\prod_{i=1}^{n} \boxed{\mathsf{v}_{\texttt{bl}i}}_{\epsilon} = (1,1)$.
- 3. Σ_{zero}^{i} : prover shows knowledge of $r_{\text{bl},i}$, $r_{\text{out},i}$, $r_{\text{in},i}$ such that $\mathsf{VerifyUpdateAcct}(\texttt{inputs}_i', \texttt{outputs}_i', 0, 0, 0; (1, r_{\texttt{bl},i}, r_{\texttt{out},i}, r_{\texttt{in},i})) = 1.$ The sub-argument can be written as follows: given $\mathsf{acct}_1 = (\mathsf{pk}, \boxed{\mathtt{v}_{\mathtt{bl}}}_1, \boxed{\mathtt{v}_{\mathtt{out}}}_1, \boxed{\mathtt{v}_{\mathtt{in}}}_1), \mathsf{acct}_2 = (\mathsf{pk}, \boxed{\mathtt{v}_{\mathtt{bl}}}_2, \boxed{\mathtt{v}_{\mathtt{out}}}_2, \boxed{\mathtt{v}_{\mathtt{in}}}_2),$

the prover knows r_{b1} , r_{out} , r_{in} such that $\boxed{v_{b1}}_1 = \boxed{v_{b1}}_2 \cdot pk^{r_{b1}}$, $\boxed{v_{out}}_1 =$ $\overline{v_{\text{out}}}$ ₂ · pk^{r_{out}}, $\overline{v_{\text{in}}}$ ₁ = $\overline{v_{\text{in}}}$ ₂ · pk^{r_{in}}. The equation is equivalent to:

 $\overline{\wedge_{i=\{\texttt{bl},\texttt{out},\texttt{in}\}}\mathsf{VerifyUpdate}(\texttt{pk},\overline{\overset{com_{2,i}}{com_{1,i}}})}$ $\frac{com_{2,i}}{com_{1,i}}$, r_i) = 1, hence can be done using ANDproofs of Σ_{vu} .

- 4. Σ_{vds}^i : prover shows knowledge of $v, r_{\text{bl},i}, r_{\text{out},i}$ such that $\text{acct}_{\epsilon,i}$ has the opposite value under commitments $\boxed{v_{b1}}$, $\boxed{v_{out}}$, denoted as com₁, com₂ respectively. This is equivalent to $\mathsf{VerifyUpdate}((g,h), \mathsf{com}_1 \cdot \mathsf{com}_2, r_{\mathsf{bl},i}+r_{\mathsf{out},i}).$ \varSigma_{vds}^i can be implemented by using Σ_{vu} .
- 5. Σ_{vdr}^{i} : prover shows knowledge of $v, r_{\text{bl},i}, r_{\text{in},i}$ such that $\text{act}_{\epsilon,i}$ has the same value under commitments $\boxed{v_{b1}}$, $\boxed{v_{in}}$, denoted as com_1, com_2 respectively. This is equivalent to $\text{VerifyUpdate}((g, h), \frac{\text{com}_1}{\text{com}_2}, r_{\text{bl},i} - r_{\text{out},i})$. Σ_{vdr}^{i} can be implemented by using Σ_{vu} .
- 6. Σ_{range} : prover shows knowledge of acct_c, v, r such that VerifyNonNegative(acct_c, v, r) = 1. In order to implement this we use Bulletproofs [\[6\]](#page-15-6).
- 7. Finally in order to prove VerifyAcct(acct,sk, bl):
	- (a) the prover shows knowledge of sk using $\Sigma_{d, \omega}$.
	- (b) Since sender may not know the randomness used to open his commitment, the prover opens the commitment with the sk and finds the value bl.
	- (c) Chooses a new randomness $r \leftarrow \mathbb{F}_p$ and constructs $\text{acc}_\epsilon = ((g, h), \text{Commit}((g, h), \text{bl}; r)).$
	- (d) Proves using Σ_{com} that these two accounts has the same bl.
	- (e) Proves using $\Sigma_{range}(\text{acct}_\epsilon, \text{bl}, r)$ that $\text{bl} \in \mathcal{V}$.
	- So $\Sigma_{range,sk} = \Sigma_{dlog} \wedge \Sigma_{com} \wedge \Sigma_{range}.$

Hence $\Sigma_2 = \Sigma_{vud} \wedge \Sigma_{\delta} \wedge (\wedge_{i=s+1}^t \Sigma_{range}(\text{acct}_{\delta,i}, \mathbf{v}_{\text{bl}_i}^{\prime}, r_{\text{bl},i})) \wedge (\wedge_{i=t+1}^n \Sigma_{zero}^i) \wedge$ $(\wedge_{i=1}^s \Sigma_{range, \textsf{sk}}(\textsf{outputs}_i', \textsf{bl}_i + \texttt{v}_{\textsf{bl}_i}, \textsf{sk})) \ \wedge \ \left(\wedge_{i=1}^s \Sigma_{vds}^i\right) \ \wedge \ \left(\wedge_{i=s+1}^t \Sigma_{vdr}^i\right) \ldots \Sigma_2 \text{ is}$ a public-coin SHVZK argument of knowledge of the relation R_2 as follows from the properties of AND-proofs.

The full SHVZK argument knowledge of Trans is then $\Sigma := \Sigma_1 \wedge \Sigma_2 \wedge \Sigma_3$.

B.5 Algorithm to create accounts

The algorithm CreateAcct(userInfo, A) in [Figure 3](#page-27-1) performs the following steps:

B.6 Delete Account Algorithm

The algorithm DelAcct(sk, userInfo, acct_D , acct_C , A_1 , A_2) in [Figure 4](#page-28-0) performs the following steps:

B.7 Auditing

The PrepareAudit algorithm in [Figure 5](#page-29-0) takes as input the user's secret key sk, the two blockchain snapshots ($state_1, state_2$), and the policy f along with the necessary information aux.

Both the Register and PrepareAudit functionalities need a NIZK argument for the statements:

- 1. Pick $r_1, r_2, r_3, r_4 \leftarrow \mathbb{F}_p^*$ and let $\vec{r} = (r_1, r_2, r_3, r_4)$. Let $\text{acct} = (\text{pk}, 0, 0, 0, 0)$ be the output of ${\sf NewAcct}({\sf userInfo}.{\sf pk}_0; \vec{r}).$
- 2. Let inputs = $\{$ userInfo $\}$ ∪ A in some canonical order. Let c, I_A be the indices of the chosen initial public key for which we wish to construct the new account, and the anonymity set in this list.
- 3. Construct \vec{v} as follows: $v_i = 0 \ \forall i \in I_A$ and $v_c = 1$.
- 4. Pick $r_5 \leftarrow \mathbb{F}_p^*$ and let outputs be the output of UpdateUser(inputs, $\vec{v}; r_5$).
- 5. Form a NIZK argument π of the relation $R(x, w)$, where x (acct, inputs, outputs), $w = (c, \vec{v}, \vec{r}, r_5)$ and $R(x, w) = 1$ if $\forall i \in {\c} \cup I_A$, userInfo_i \in inputs, user
Info/ \in outputs we have that:

 $\mathsf{VerifyUpdateUser}(\mathsf{userInfo}_i', \mathsf{userInfo}_i, 0; r_5) = 1 \,\, \forall i \in \mathtt{I_A}$

- \wedge VerifyUpdateUser $($ userInfo $_{{\rm c}}^{\prime},$ userInfo $_{{\rm c}},1;r_5)=1$
- \wedge VerifyUpdate(acct.pk, userInfo $_c$.pk $_0, r_1) = 1$
- \wedge Commit(acct.pk, 0; r_2) = acct.com_{bl}
- \wedge Commit(acct.pk, 0; r_3) = acct.com_{out} \wedge Commit(acct.pk, 0; r_4) = acct.com_{in}

The final transaction returned by the algorithm is $tx_{CA} = (act, inputs, outputs, \pi)$.

Fig. 3. The CreateAcct algorithm.

– VerifyKP(pk,sk): prover shows knowledge of a valid (pk,sk) key-pair. The corresponding language can be written as:

$$
L_{vu} := \{ pk = (X = g^r, Y = g^{r \cdot sk}) \mid \exists sk \text{ s.t. } Y = X^{\text{sk}} \}
$$

This can be proven through Σ_{dlog} with arguments (X, Y, sk) .

– VerifyCom(pk, com, sk, v): prover shows knowledge of secret key sk that opens the commitment com to value v . The corresponding language can be written as:

$$
L_{open(sk)} := \{(\texttt{com} = (X = h^r, Y = g^v h^{sk \cdot r}), v) \mid \exists \texttt{sk s.t. } Y/g^v = X^{\texttt{sk}}\}
$$

This can be proven through Σ_{dlog} with arguments $(X, Y/g^v, \text{sk})$.

The argument needed for Register results from the composition of these Σ protocols and a range proof for showing that $bl \in V$. The PrepareAudit proof uses the same combination of these Σ -protocols and appropriate range proofs for each policy $f_{\text{slimit}}, f_{\text{rlimit}}, f_{\text{open}}, f_{\text{tzlimit}}, f_{\text{np}}.$

C Security Proofs

C.1 Details of bookkeeping functionalities

The bookkeeping functionalities which are used in Game [1,](#page-11-0) Game [2](#page-12-0) Game [3](#page-13-0) are analyzed in Figure [4:](#page-30-0)

- 1. Ensure that VerifyKP(sk, userInfo.pk) = $1 \wedge$ VerifyKP(sk, acctc.pk) = $1 \wedge$ Verify $KP(\text{sk}, \text{acct}_{D}.\text{pk}) = 1.$
- 2. For the account acct_D , calculate the opening of the commitments $\text{actor}_{\text{out}}$, actor_{in} , com_{in} , denoted out_{D} , in_{D} , using the secret key sk.
- 3. Let $\text{inputs}_{\text{UTXOSet}} = \{\text{actor}_{\text{C}}\} \cup \mathbf{A}_1 \text{ in some canonical order.}$ Let c^* , \mathbf{I}_{A1} denote the indices of the account to be added the information and the accounts of the anonymity set in this list.
- 4. Construct $\overrightarrow{v_{\text{bl}}}, \overrightarrow{v_{\text{out}}}, \overrightarrow{v_{\text{in}}}$ as follows:
	- $-\overrightarrow{v_{b1}} = 0 \ \forall i \in \{c^*\} \cup I_{A1}$
	- $-\overline{v_{\text{out}}} = 0 \ \forall i \in I_{A1} \text{ and } v_{\text{out }c^*} = \text{out}_D$
	- $-\overline{v_{\text{in}}} = 0 \ \forall i \in I_{A1} \text{ and } v_{\text{in}_c^*} = \text{in}_D$
- 5. Pick $r_1, r_2, r_3, r_4 \leftrightarrow \mathbb{F}_p^*$ and let $\vec{r} = (r_1, r_2, r_3, r_4)$. Let outputs_{UTXOSet} be the output of UpdateAcct(inputs_{UTXOSet}, $\overline{v_{b1}}$, $\overline{v_{out}}$, $\overline{v_{in}}$, $\overline{v_{in}}$) in some canonical order.
- 6. Let $\psi: \{1, ..., n\} \to \{1, ..., n\}$ be the implicit permutation mapping inputs_{UTXOSet} into outputs_{UTXOSet}; such that accounts $\text{acci}_i \in \text{inputs}_{UTXOSet}$ and $\text{acci}_{\psi(i)}^{\vee} \in$ outputs $_{\text{UTXOSet}}$ share the same secret key.
- 7. Form a NIZK argument π_1 of the relation $R(x, w)$, where
	- $x = (\text{actor, inputs}_{\text{UTXOSet}}, \text{outputs}_{\text{UTXOSet}}, w = (\text{sk}, \text{out}_D, \text{in}_D, \vec{r}, \psi, c^*, \text{I}_{A1}), \text{ and}$ $R(x, w) = 1$ if
		- VerifyKP(sk, acct_D.pk) = 1 \land VerifyKP(sk, acct_{c*}.pk) = 1
		- \wedge Verify \bigcup pdate $\mathsf{Acct}(\mathsf{acct}'_{\psi(i)}, \mathsf{acct}_i, 0, 0, 0; \overrightarrow{r}) = 1 \; \forall i \in \mathtt{I}_{\mathtt{A1}}$
		- \wedge VerifyUpdateAcct(acct'_{$\psi(c^*)$}, acct c^* , 0, out_D, in_D; $\vec{r}) = 1$
		- \wedge VerifyCom(acct_D.pk, acct_D.com_{bl}, (sk, 0)) = 1
- 8. Let inputs_{UserSet} = {userInfo} ∪ A₂ in some canonical order. Let s^* , I_{A2} denote the indices of the chosen initial public key for which we wish to construct the new account, and the anonymity set in this list.
- 9. Construct \vec{v} as follows: $v_i = 0$ $\forall i \in I_{A2}$ and $v_{s^*} = -1$.
- 10. Pick $r \leftarrow \mathbb{F}_p^*$ and let outputs_{UserSet} be the output of UpdateUser(inputs_{UserSet}, \vec{v} ; *r*).
- 11. Form a NIZK argument π_2 of the relation $R(x, w)$, where x $(\texttt{inputs}_{\textsf{UserSet}}, \texttt{outputs}_{\textsf{UserSet}}), w = (\textsf{sk}, r, s^*, \texttt{I}_{\texttt{A2}}) \text{ and } R(x, w) = 1 \text{ if }$ $\forall i \in \{s^*\} \cup I_{A2}$ userInfo_i \in inputs_{UserSet}, userInfo[']_i \in outputs_{UserSet} we have that:
	- $\mathsf{VerifyKP}(\mathsf{sk},\mathsf{userInfo}_{s^*}.\mathtt{pk}_0) = 1$ \wedge VerifyUpdateUser $($ userInfo $_i',$ userInfo $_i,0;r) = 1 \,\, \forall i \in \mathtt{I_{A2}}$ \wedge VerifyUpdateUser(userInfo $\zeta_{s^*},$ userInfo $_{s^*}, -1; r) = 1$

The final transaction returned by the algorithm is $tx_{DA} = (inputs_{UTXOSet}, outputs_{UTXOSet}, inputs_{UTXOSet}, inputs_{UserSet}, outputs_{UserSet}, \pi = (\pi_1, \pi_2)).$

Fig. 4. The DelAcct algorithm.

The algorithm auditInfo \leftarrow PrepareAudit(sk, pk₀, state₁, state₂, (*f*, aux)) performs the following steps:

- 1. Ensure that $VerifyKP(sk, pk_0)$. For each snapshot state_j, $j = 1, 2$ find the userInfo_j that contains \mathtt{pk}_0 , and calculate $\texttt{\#accs}_j = \mathsf{OpenCom}(\textsf{sk}, \textsf{userInfo}.|\texttt{\#accs}_j|)$
- 2. For $j = 1, 2$ re-randomize the accounts in UTXOSet $_j =$ state_j.UTXOSet. In particular:
	- (a) Let inputs, be all the accounts of $UTXOSet_j$.
	- (b) Sample $r_1, r_2, r_3, r_4 \leftarrow \mathbb{F}_p$ and let $\vec{r} = (r_1, r_2, r_3, r_4)$.
	- (c) Compute $\texttt{outputs}_j = \text{UpdateAcct}(\texttt{inputs}_j, \vec{0}, \vec{0}, \vec{0}; r).$
	- (d) Let $\psi : \{1, ..., |UTXOSet_j|\} \rightarrow \{1, ..., |UTXOSet_j|\}$ be the implicit permutation mapping inputs_j into outputs_j; such that accounts $\text{acct}_k \in \text{inputs}_j$ and $\mathsf{acct}'_{\psi(k)} \in \mathsf{outputs}_j$ share the same secret key.
	- (e) Form a NIZK argument π_p of the relation $R(x, w)$, where $x = (inputs_j, outputs_j), w = (\psi, r), \text{ and } R(x, w) = 1 \text{ if }$ $\begin{array}{l} \mathcal{L} \longrightarrow \text{Tr}(\mathcal{L} \setminus \mathcal{L} \setminus \math$

The re-randomized sets of accounts are $\texttt{outputs}_1, \texttt{outputs}_2.$

3. For $j = 1, 2$, find the set of accounts $A_j = \{\mathsf{acct}'_i\}_{i=1}^{\mathsf{faces}_j}$ from $\mathsf{outputs}_j$ that belong to the user. That is, ∀acct ∈ $\texttt{outputs}_j,$ if $\textsf{VerifyKP}(\textsf{acct}.\textsf{pk},\textsf{sk}) = 1,$ then add \textsf{acct} to A_i .

4. Form a NIZK argument π_1 of the relation $R(x, w)$, where $x =$ $(\text{pk}_0, \{\text{\#aces}_j, \text{\#aces}_j\}, \{\text{act}'_{ji}\}_{i=1}^{\text{\#aces}_j}\}_{j=1}^2), w = (\textsf{sk}) \text{ and } R(x, w) = 1 \text{ if: }$

> $\mathsf{VerifyCom}(\mathrm{pk}_0, \big\vert \, {\tt#acos}_j \big\vert, (\mathsf{sk}, \# \mathsf{acos}_j)) = 1 \,\, \forall j \in \{1,2\}$ \wedge VerifyKP $(\texttt{pk}_0, \textsf{sk}) = 1$

$$
\wedge \text{VerifyKP}(\texttt{acct}'_{ji}.\textsf{pk},\textsf{sk}) = 1 \; \forall i \in \{1,\dots,\texttt{\#acos}_j\}, \; \forall j \in \{1,2\}
$$

If $f \in \{f_{\text{slimit}}, f_{\text{rlimit}}, f_{\text{np}}\}$ then:

4. For $j = 1, 2$ calculate out^{*} $\left[\frac{*}{j}\right]=\prod_{i=1}^{\texttt{\#accs}}_j \mathsf{acct}_{ji}.\boxed{\mathsf{out}},\boxed{\mathsf{in}_j^*}$ $\overline{\mathcal{C}_{j}^{*}} = \prod_{i=1}^{\# \texttt{accs}_j} \mathsf{acct}'_{ji} . \overline{\mathtt{in}} \, .$ Then calculate $\vert \text{out}^* \vert$ $= |\verb"out"_{2}|$ $\sqrt{\mathsf{out}_1^*}$ $, |in^*$ $\,,\big|\,\texttt{in}^*\,\big|\!=\!\big|\,\texttt{in}_2^*\,\big|\cdot$ $\sqrt{ }$ \mathtt{in}_1^* $\bigcap \begin{array}{c} -1 \end{array}$. Finally, calculate $\mathsf{out}^* = \mathsf{OpenCom}(\mathsf{sk}, |\mathsf{out}^*|), \mathsf{in}^* = \mathsf{OpenCom}(\mathsf{sk}, |\mathsf{in}^*|).$ These values represent the total amount of coins that the user spent/received in the selected period of time. 5. Form a NIZK argument π_2 of the relation $R(x, w)$ where x $(\{\mathsf{acct}'_{1i}\}_{i=1}^{\mathsf{Haccs}_j}, \{\mathsf{acct}'_{2i}\}_{i=1}^{\mathsf{Haccs}_j}, \boxed{\mathsf{out}^*}, \boxed{\mathsf{in}^*}, \mathsf{aux}), w \hspace{20pt} = \hspace{20pt} (\mathsf{out}^*$ (out^*, in^*)) and $R(x, w) = 1$ if: $f({\tt pk}_0,({\sf state}_1,{\sf state}_2), {\tt aux}) = 1$ If $f \in \{f_{\text{txlimit}}, f_{\text{open}}\}$ then: 4. For $j = 1, 2$ calculate $\left[\mathbf{bl}_j^*\right] = \prod_{i=1}^{\# \text{access}_j} \text{acct}'_{ji}$. Then calculate $\left[\mathbf{bl}^*\right] =$ $\overline{{\tt b}{\tt l}_2^*}\big\vert\!\cdot\! \left(\overline{\tt b}{\tt l}_1^*\right)\!\right)^{-1} \text{ and } {\tt b}{\tt l}^* = {\sf OpenCom}({\sf sk},\overline{\sf b}{\tt l}^*)\!\!\!.$ 5. Form a NIZK argument π_2 of the relation $R(x, w)$ where $x =$

$$
(\{\mathsf{acct}'_{1i}\}_{i=1}^{\mathsf{\#accs}_j}, \{\mathsf{acct}'_{2i}\}_{i=1}^{\mathsf{\#accs}_j}, \overline{\mathsf{b1}^*}, \mathsf{aux}), w = (\mathsf{b1}^*) \text{ and } R(x,w) = 1 \text{ if: }
$$

 $f(\text{pk}_0,(\text{state}_1,\text{state}_2),\text{aux})=1$

The final output is $\sf{audithfo} = (\tt{outputs}_1, \tt{outputs}_2, \tt{\#accs}_1, \tt{\{act'_1}_i\}_{i=1}^{\#accs}, \tt{\#accs}_2,$ $\{\mathsf{acct}'_{2i}\}_{i=1}^{\mathsf{\#accs}}, \pi = (\pi_p, \pi_1, \pi_2)).$ 30

C.2 Details of oracles

The oracles where the adversary has access in Game [1,](#page-11-0) Game [2](#page-12-0) Game [3](#page-13-0) are analyzed in Figure [5:](#page-32-0)

C.3 Full proof of anonymity

Before we give the proof of anonymity, we first recall a definition for indistinguishability of UPK scheme [\[15\]](#page-16-1).

Definition 4. The advantage of the adversary in winning the indistinguishability game is defined as:

$$
\mathsf{Adv}_{\mathcal{A}}^{\mathrm{ind}}(\lambda)=\mid \Pr[\mathsf{Exp}_{\mathcal{A}}^{ind}((\lambda))=1]-\frac{1}{2}\mid
$$

A DPS satisfies indistinguishability if for every PPT adversary A, $\text{Adv}_{\mathcal{A}}^{\text{ind}}(\lambda)$ is negligible in λ .

Note that in indistinguishability game the challenger can update many times the pk^* before creating pk_0 due to the fact that even with more updates the pk_0 can be described as an update of pk[∗] with a different randomness.

Lemma 1. The constructed UPK scheme satisfies $\frac{1}{4}$ if the DDH assumption holds in (\mathbb{G}, q, p) .

Proof of this lemma can be found in [\[15\]](#page-16-1).

Theorem 1. AQQUA satisfies anonymity, as defined in [Definition 1](#page-11-1)

Proof. We prove the theorem using a sequence of 14 hybrid games, as follows. Hybrid 0 and Hybrid 7 are the anonymity game for $b = 0, b = 1$ respectively. Each of the rest hybrids differs in oracles' functionalities in a way that the successive hybrids are indistinguishable from the view of the adversary. We use these hybrids to prove that the adversary cannot distinguish anonymity game for $b = 0$ and anonymity game with $b = 1$.

Hybrid 0. The anonymity game for $b = 0$.

Hybrid 1. Same as Hybrid 0, but here we run the NIZK extractor on each transaction generated by the adversary. That means, when A runs the OApplyTrans(tx) Oracle, the Oracle verifies tx by running VerifyTrans(tx, state) depending on the transaction tx and if it is successful the oracle runs state^{\prime} \leftarrow ApplyTrans(state, tx), as well as uses the NIZK extractor to extract the witness used to generate tx, including sk.

Hybrid 2. Same as Hybrid 1, but here the zero-knowledge arguments of the each transaction is replaced with the output of the corresponding simulator of the zero-knowledge property of NIZK. In order to achieve this we change the following oracles' functionality:

Algorithm 5: Oracles for security definitions

```
Oracle OCorrupt (pk, state)
               // pk should be a key of an account or user information in
       state, aborts otherwise
     sk ← findSecretKey(pk,state)
     honest \leftarrow honest \setminus {sk}
     corrupt ← corrupt ∪ {sk}
     return sk
Oracle ORegister()
     state ← bookkeeping.states[−1] // most recent state of bookkeeping
     (sk, userInfo, acct, \pi) \leftarrow Register()
     if VerifyRegister(userInfo, acct, \pi, state) = 0 then
      return ⊥ // cannot be registered given current state
     entries ← entries ∪ {sk}
     honest ← honest ∪ {sk}
      \mathsf{state}' \leftarrow \mathsf{ApplyRegister}(\mathsf{userInfo}, \mathsf{acct}, \mathsf{state});\, \mathsf{states} \leftarrow \mathsf{states} \cup [\mathsf{state}']return state′
Oracle OCreateAcct (userInfo, A)
     state ← bookkeeping.states[−1] // most recent state of bookkeeping
     tx_{CA} \leftarrow CreateAcct(userInfo, A)if VerifyTrans(tx_{CA}, state) = 0 then
      return ⊥ // transaction cannot be applied to state
      \mathsf{state}' \leftarrow \mathsf{ApplyTrans}(\mathsf{tx}_{\mathsf{CA}},\mathsf{state});\, \mathsf{states} \leftarrow \mathsf{states} \cup [\mathsf{state}']return tx_{CA}, state<sup>\prime</sup>
Oracle ODelAcct (userInfo, \text{act}_C, \text{act}_D, A_1, A_2)
     state ← bookkeeping.states[−1]
     \mathsf{sk} \gets \mathsf{findSecretKey}(\mathsf{acct}_{\mathsf{C}})tx_{DA} \leftarrow DelAcct(sk, userInfo, acctc, acct_D, A_1, A_2)
     if VerifyTrans(tx_{DA}, state) = 0 then
      return ⊥ // transaction cannot be applied to state
      \mathsf{state}' \leftarrow \mathsf{ApplyTrans}(\mathsf{tx_{DA}},\mathsf{state});\, \mathsf{states} \leftarrow \mathsf{states} \cup [\mathsf{state}']return tx_{DA}, state<sup>\prime</sup>
Oracle OTrans (S, R, \vec{v}_S, \vec{v}_R, A)state ← bookkeeping.states[−1] // most recent state of bookkeeping
     for sk ∈ entries do
          Take an arbitrary \text{acct} \in Sif VerifyKP(\text{sk}, \text{acct}.\text{pk}) = 1 then
                tx \leftarrow Trans(S, R, \vec{v_s})// If sk is not the owner of all
                 accounts in S, the transaction will not be created.
                if VerifyTrans(tx, state) = 0 then
                 \parallel return \perp // transaction cannot be applied to state
                \mathsf{state}' \leftarrow \mathsf{ApplyTrans}(\mathsf{tx},\mathsf{state});\, \mathsf{states} \leftarrow \mathsf{states} \cup [\mathsf{state}']return tx, state'
     return ⊥
Oracle OApplyTrans(tx)
     if VerifyTrans(tx, state) = 0 then
      return ⊥
     state<sup>\prime</sup> ← ApplyTrans(tx, state)
      states \leftarrow states \cup [state^{\prime}]; \bold{return} state^{\prime}\bf{Oracle} \bf{OP}repare\bf{A}udit(\text{pk}_0, \text{state}_1, \text{state}_2, f, \text{aux})\mathsf{sk} \leftarrow \mathsf{findSecretKey}(\mathtt{pk}_0, \mathsf{state}_1)\mathbf{if} \; \mathsf{state}_1, \mathsf{state}_2 \in \mathsf{states} \land \mathsf{state}_1 \; \mathbf{is} \; \mathbf{older} \; \mathbf{than} \; \mathsf{state}_2 \; \mathbf{then}\mathsf{audithfo} \leftarrow \mathsf{PrepareAudit}(\mathsf{sk}, \allowbreak \mathsf{pk}^3_0 \! \mathsf{3state}_1, \mathsf{state}_2, f, \allowbreak \mathsf{aux})\bf{if} \sf VerifyAudit(\mathbf{pk}_0, state_1, state_2, (f, aux), audithfo) \bf{then}| return auditInfo
      \mathbf{return} \perp \: \: \: // \:\: \mathsf{pk}_{0} was invalid for the snapshots, state_1, \mathsf{state}_{2} were
       not valid or f was not satisfied
```
Game 6: Indistinguishability game $\text{Exp}_{\mathcal{A}}^{ind}(\lambda)$

Input : λ Output: $\{0,1\}$ $b \leftarrow \{0, 1\}$ $(\mathsf{pk}^*,\mathsf{sk}^*) \leftarrow \mathsf{KGen}()$ $r \leftarrow \mathbb{F}_p^*$ $\mathsf{pk}_0 \leftarrow \mathsf{Update}(\mathsf{pk}^*; r)$ $(\mathsf{pk}_1, \mathsf{sk}_1) \leftarrow \mathsf{KGen}()$ $b' \leftarrow \mathcal{A}(\mathsf{pk}^*, \mathsf{pk}_b)$ return $(b = b')$

- when A or the challenger creates tx through the OTrans $(S, R, \overrightarrow{v_s}, \overrightarrow{v_R}, A)$ Oracle, when A or the enancinger ereates is difficult in \circ rans(b, n, vg, v_R, A) Oracle,
the Oracle runs tx \leftarrow Trans(sk, S, R, $\vec{v_s}$, $\vec{v_s}$, A), but replaces the zero-knowledge arguments in tx with a simulated argument.
- when A or the challenger creates tx through the OCreateAcct(userInfo, A) Oracle, the Oracle runs $tx \leftarrow$ CreateAcct(userInfo, A), but replaces the zeroknowledge arguments in tx with a simulated argument.

Hybrid 3. Same as Hybrid 2, but now the challenger replaces the potential senders' and receivers' accounts of the challenge transaction tx_0 (acct₀, acct₁, acct₀, acct₁), with new accounts that have a freshly created key pair (sk, pk) derived from the output of the KGen(). In order to achieve this we change the following oracles' functionality:

- when A creates one of these accounts acc _i through the OTrans Oracle (these accounts are presented in tx.outputs), the Oracle runs tx \leftarrow Trans(sk, S, R, $\vec{v_s}, \vec{v_R}, A$), $(\mathsf{pk}'_i, \mathsf{sk}'_i) \leftarrow \mathsf{KGen}$ and then return tx' , where $\mathsf{tx}' = \mathsf{tx}$ except that each $\mathsf{acct}_i \in \mathsf{Ext}$ $\{ \text{act}_0, \text{act}_1, \text{act}_0', \text{act}_1' \}$ is replaced with $\text{act}_i' = (\text{pk}_i', \text{com}_{\text{bl}i}, \text{com}_{\text{out}i}, \text{com}_{\text{ini}})$.
- when A creates one of these accounts acct_i through the OCreateAcct Oracle, the Oracle runs $tx \leftarrow$ CreateAcct(userInfo, A), $(\mathsf{pk}'_i, \mathsf{sk}'_i) \leftarrow$ KGen and then return tx' , where $tx' = tx$ except that each $\text{acct}_i \in \{\text{acct}_0, \text{acct}_1, \text{acct}'_0, \text{acct}'_1\}$ is replaced with $\mathsf{acct}'_i = (\mathsf{pk}'_i, \boxed{0}, \boxed{0}, \boxed{0})$.

Hybrid 4. Same as Hybrid 3, but here the challenger replaces also the commitments of the accounts ($\mathsf{actor}_0, \mathsf{actor}_1', \mathsf{actor}_1'$) with newly created commitments to the same values with different randomness. In order to achieve this we change the following oracles' functionality:

– when A creates one of these accounts acct_i through the OTrans Oracle (these accounts are presented in tx.outputs), the Oracle runs tx \leftarrow Trans(sk, S, R, $\vec{v_s}$, $\vec{v_s}$, A), $(r_1, r_2, r_3) \leftarrow$ $\mathbb{F}_p^*,$ bl $_i$ \leftarrow OpenCom(sk, acct $_i$.com $_{\text{b1}}$), out $_i$ \leftarrow OpenCom(sk, acct $_i$.com $_{\text{out}}$), $\dot{m}_i \leftarrow \text{OpenCom}(\textsf{sk}, \textsf{act}_i.\textsf{com}_{\textsf{in}}), \textsf{com}_{\textsf{bl}}' \leftarrow \textsf{Commit}(\textsf{pk}', \textsf{bl}_i; r_1), \textsf{com}_{\textsf{out}}' \leftarrow$

Commit(pk', out_i; r_2), com'_{in} \leftarrow Commit(pk', in_i; r_3) and then return tx', where $tx' = tx$ except that each $\mathsf{acct}_i \in \{\mathsf{acct}_0, \mathsf{acct}_1, \mathsf{acct}'_0, \mathsf{acct}'_1\}$ is replaced with $\mathsf{acct}' = (\mathsf{pk}, \mathsf{com}'_{\mathsf{b1}}, \mathsf{com}'_{\mathsf{out}}, \mathsf{com}'_{\mathsf{in}}).$ ($\mathsf{pk} = \mathsf{pk}'$ as in the Hybrid 3).

– when A creates one of these accounts acct_i through the OCreateAcct Oracle, the Oracle runs

 $\mathsf{tx} \leftarrow \mathsf{CreateAcct}(\mathsf{userInfo}, \mathtt{A}), (r_1, r_2, r_3) \leftarrow \mathbb{s} \, \mathbb{F}_p^*, \, \mathsf{com}_\mathtt{bl}' \leftarrow \mathsf{Commit}(\mathsf{pk}'0; r_1), \, \mathsf{com}_\mathtt{out}' \leftarrow$ Commit(pk', 0; r_2), com'_{in} \leftarrow Commit(pk', 0; r_3) and then return tx', where $tx' = tx$ except that each $\mathsf{acct}_i \in \{\mathsf{acct}_0, \mathsf{acct}_1, \mathsf{acct}'_0, \mathsf{acct}'_1\}$ is replaced with $\mathsf{acct}' = (\mathsf{pk}, \mathsf{com}'_{\mathsf{b1}}, \mathsf{com}'_{\mathsf{out}}, \mathsf{com}'_{\mathsf{in}}).$ ($\mathsf{pk} = \mathsf{pk}'$ as in the Hybrid 3).

Hybrid 5. Same as Hybrid 4, but here also the updated accounts of $(\textsf{acct}_0, \textsf{acct}_1, \textsf{acct}'_0, \textsf{acct}'_1)$ in the challenge tx.outputs are replaced by accounts with freshly created public key pk′ .

Hybrid 6. Same as Hybrid 5, but here also the updated accounts of $(\textsf{acct}_0, \textsf{acct}_1, \textsf{acct}'_0, \textsf{acct}'_1)$ in the challenge tx.outputs are replaced by accounts with freshly created commitments to the same value.

Afterwards, we create Hybrids 7-13 that are the same with Hybrids 0-6 with the difference that are made for the anonymity game with $b = 1$.

Note that in Hybrid 6 and in Hybrid 13 all accounts of the potential senders' and receivers' accounts of the challenge transaction tx_b (both in inputs and outputs) are fresh accounts, where in outputs have been generated with values corresponding to the case $b = 0 - b = 1$.

Now we will prove that A has negligible advantage of distinguish Hybrid 0 and Hybrid 7.

Lemma 2. Hybrid 0 and Hybrid 1 are indistinguishable.

Corollary 1. Hybrid 7 and Hybrid 8 are indistinguishable.

Proof. The adversary's view in the two hybrids' game are identical.

Lemma 3. Hybrid 1 and Hybrid 2 are indistinguishable.

Corollary 2. Hybrid 8 and Hybrid 9 are indistinguishable.

Proof. Let A be an adversary that can distinguish Hybrid 1 and Hybrid 2 with advantage ϵ . We construct an adversary β that breaks the zero-knowledge property of the NIZK proof π of transaction tx with probability ϵ .

Let $O_{zk}(\cdot)$ be an oracle that on input (tx.inputs, tx.outputs) creates a valid NIZK argument for the transaction. Then B wins if they can decide wether $O_{z\mathsf{k}}(\cdot)$ is a prover or simulator oracle.

 β takes as input the $O_{z_k}(\cdot)$ and runs as follows:

1. B generates state \leftarrow Setup(λ);

- 2. When $\mathcal A$ queries the $\mathsf{OTrans}(S,R,\overrightarrow{v_S},\overrightarrow{v_R},\mathtt{A})$ oracle then $\mathcal B$ runs tx $\leftarrow \mathsf{Trans}(\mathsf{sk},S,R,\overrightarrow{v_S},\overrightarrow{v_R},\mathtt{A})$ with the difference that B replace the proof with the output of $O_{2k}(tx|inputs], tx[outputs])$
- 3. When A queries the OCreateAcct(userInfo, A) oracle then B runs tx \leftarrow CreateAcct(userInfo, A) with the difference that B replace the proof with the output of $O_{z_k}(t \times [inputs], tx[outputs])$
- 4. B runs $b \leftarrow \mathcal{A}(state);$

If A answers Hybrid 0 then $O_{\mathbf{z}k}(\cdot)$ is a prover oracle. If A answers Hybrid 1 then $O_{\mathbf{z}\mathbf{k}}(\cdot)$ is a simulator oracle. So B wins with probability ϵ .

Lemma 4. Hybrid 2 and Hybrid 3 are indistinguishable.

Corollary 3. Hybrid 9 and Hybrid 10 are indistinguishable.

Proof. Note that A cannot distinguish Hybrid 2 and Hybrid 3 from the fact that commitments are under different public key on the grounds that this breaks the key-anonymous property of the commitment scheme. Let A be an adversary that can distinguish Hybrid 2 and Hybrid 3 with advantage ϵ . We construct an adversary β that breaks the indistinguishability property of the UPK scheme with probability ϵ .

In order to create \mathcal{B} , we define five sub-hybrids. Let h_0 be Hybrid 2 and for each $i \in \{1, 2, 3, 4\}$ h_i would be a sub-hybrid where we replace the account $\mathsf{acct}_0, \mathsf{acct}_1, \mathsf{acct}_0', \mathsf{acct}_1'$ respectively. In hybrid h_4 all of the accounts will be changed, therefore h_4 is Hybrid 3. Lets A be an adversary that can distinguish h_i from h_{i+1} . Let acct_c be the account that we are replacing in this hybrid. Then: β gets as input the tuple (acct^{*}, acct_b) from the indistinguishability game and runs as follows:

- 1. B generates state \leftarrow Setup(λ).
- 2. when A uses the ORegister Oracle to create the initial account that share the same secret key with acct_c , $\mathcal B$ replaces this account with acct^* .
- 3. when A uses OTrans or OCreateAcct Oracle to create the account acc_c , β replaces acct_c with acct_b .
- 4. B reply to all other queries in the oracles as in the Hybrid h_0 .
- 5. B outputs $b' \leftarrow A(\text{state})$.

We know that A did not query the corrupt oracle on acct_c or on any other account that shares the same secret key with acc_c cause it would have immediately lost the anonymity game. Note that if $b = 0$ then the distribution of the game is the same as hybrid h_i and if $b = 1$ then the game has the same distribution as hybrid h_{i+1} . Hence β answer b' and solves the indistinguishability game with probability ϵ .

Lemma 5. Hybrid 3 and Hybrid 4 are indistinguishable.

Corollary 4. Hybrid 10 and Hybrid 11 are indistinguishable.

Proof. The only difference from this two Hybrids are the randomness to the commitments of the real participants accounts. Therefore, they produce a computationally indistinguishable distribution, due to the hiding property if the used commitment scheme.

Corollary 5. Hybrid 4 and Hybrid 5 are indistinguishable. Hybrid 11 and Hybrid 12 are indistinguishable. It can be proven the same way as Hybrid 2 and Hybrid 3 are indistinguishable.

Corollary 6. Hybrid 5 and Hybrid 6 are indistinguishable. Hybrid 12 and Hybrid 13 are indistinguishable. It can be proven the same way as Hybrid 3 and Hybrid 4 are indistinguishable.

Lemma 6. Hybrid 6 and Hybrid 13 are indistinguishable.

Proof. Hybrid 6 and Hybrid 13 differ to (1) the accounts that are included in P and in A as well as to (2) the balances that are stored in the real participants' accounts in the challenge query ($\mathsf{acct}_i = \in \{\mathsf{acct}_0, \mathsf{acct}_1, \mathsf{acct}_0', \mathsf{acct}_1'\})$). Concerning the former (1) , in both Hybrids the **inputs** that A sees is obtained by permuting $(P_x \cup A_x)$ with a random permutation ψ . But the union of these set in both cases $(x = \{0, 1\})$ produces identical distributions. As a result A cannot distinguish the two Hybrids from (1). The second change (2) produces a computationally indistinguishable distribution, due to the hiding property of the commitment scheme. Therefore, if A could distinguish these Hybrids based on (2) then $\mathcal A$ could break the hiding property of Commit.

Using the above lemmas and the triangle inequality, we prove that there is not a PPT adversary A that can distinguish Hybrid 0 and Hybrid 7 with more than negligible advantage.

C.4 Full proof of theft prevention

Theorem 2. AQQUA satisfies theft prevention, as defined in [Definition 2.](#page-12-1)

Proof. Assume that there exists a PPT $\mathcal A$ that wins the theft prevention game of Game [2](#page-12-0) with non-negligible probability. Using the notation of the game, we have that A outputted a valid transaction tx that verifies and that results in one of the three winning conditions of the game being satisfied.

We have that $tx = (inputs, outputs, \pi)$, where π is a ZK-proof for the relation $R(x, w)$ as defined in [Figure 2,](#page-22-0) with $x = ($ inputs, outputs) and $w =$ (sk, b1, out, in, $\overline{v_{\text{bl}}}$, $\overline{v_{\text{out}}}$, $\overline{v_{\text{in}}}$, \overline{r} , ψ , I_s^* , I_h^* , I_h^*).

From the soundness property of the NIZK argument of the Trans algorithm, we can extract a witness $\frac{1}{1}$ \rightarrow

 $w^* = (\mathsf{sk}^*, \mathsf{b1}^*, \cdots,$ $v_{\text{bl}}^{*i}, \cdots,$ $\overline{r^*}, \dots$) such that $R(x, w^*) = 1$.

Let $\text{acct} \in \text{inputs}$ be the account such that $\text{VerifyKP}(\text{sk}^*, \text{acct}.\text{pk}) = 1$. We divide into two cases.

1. It holds that $sk^* \in$ honest. In this case, we construct an adversary β that breaks the unforgeability property of the UPK scheme with non-negligible probability.

The reduction works as follows. The adversary β takes as input a public key pk[∗] . It also keeps a directed tree with root (pk[∗] , 1) and whose nodes will be tuples of the form (pk, r) . The tree will be updated so that for every edge of the form $((\mathsf{pk}_1, \cdot), (\mathsf{pk}_2, r_2))$ it will hold that VerifyUpdate $(\mathsf{pk}_2, \mathsf{pk}_1, r_2) = 1$. β answers to \mathcal{A} 's oracle queries as follows.

- When A queries the ORegister oracle and this query results in the Register algorithm to generate sk^* , \mathcal{B} replaces userlnfo.p k_0 with pk^* , and when NewAcct is called in the procedure, β gives as input pk^{*}. The adversary β stores the public key of the newly created account and the randomness used as a child of $(\mathsf{pk}^*, 1)$ in the tree. For the rest of the ORegister queries, β answers honestly.
- When A queries the OCreateAcct oracle for an account whose public key pk is contained in a leaf of the tree, β answers honestly and adds a child to the leaf, composed of the updated public key of the updated account and the randomness used.
- When A queries the OTrans oracle, the adversary B acts as follows.
	- ∗ If the public keys of the accounts in S are contained in leaves of the tree, β creates an outputs set and creates a simulated proof for the transaction. β also updates the tree by creating new children containing the updates of the public keys and the randomness.
	- ∗ If there exist public keys of accounts in the anonymity set that are contained in leaves of the tree, β creates new children containing the updates of the public keys and the randomness.
- When A queries the OApplyTrans with a transaction whose inputs contain a leaf of the tree, β uses the proof contained in the transaction to extract the witness. Then, β creates new children for the updates of the public keys, storing also the randomness of the witness.

• For the rest of the oracle queries, β answers honestly.

Finally, when A outputs the transaction x of the theft prevention game, β finds the $\text{acct} \in \text{inputs}$ for which $\text{VerifyKP}(\textsf{sk}^*, \textsf{acct}.\textsf{pk}) = 1$, and finds the leaf (pk, r) of the tree for which $acute,$ $p k = pk$. Let r' be the multiplication of all randomnesses stored in the path from that leaf to the root. β returns $(\mathsf{pk}, r').$

If $\mathcal A$ wins the theft prevention game, we have that $\mathsf{VerifyKP}(pk, sk^*) = 1$ and VerifyUpdate(pk, pk^{*}, r') = 1. Since A can win with non-negligible probability, β breaks unforgeability with non-negligible probability.

2. It holds that $sk^* \in \text{corrupt.}$

Assume w.l.o.g. that the transaction tx that A outputs is the first transaction that results in winning the game (that is, there is no transaction submitted to OApplyTrans oracle prior to this point that would result in A winning). Since A wins the game, we have that the sum of the openings of the committed balances of all the accounts (stored in the bookkeeping) of inputs is different from those of outputs.

From the soundness property of the NIZK argument of the Trans algorithm, we have that for every sender account acct' of outputs, VerifyAcct(acct', sk^{*}, bl^{*}+ $v_{\text{bl}}^{\prime *}$, \cdot , \cdot) = 1.

Since VerifyAcct returns 1, and also $\sum_{v_{b1}'} \overrightarrow{v_{b1}} = 0$, and since A wins the game, there exists an account $\texttt{acct} \in \texttt{outputs}$ for which $\texttt{acct.com}_{\texttt{bl}}$ has two different openings: one resulting from the bookkeeping, and one derived from the extracted witness (one of the values of the form $b1^* + v_{b1}^{\prime *}$ for some sender account). This trivially breaks the binding property of the commitment scheme.

C.5 Full proof of audit soundness

Theorem 3. AQQUA satisfies audit soundness, as of [Definition 3](#page-13-1)

Proof. Assume that there exist a PPT A that wins the audit soundness game of Game [3](#page-13-0) with non-negligible probability. Using the notation of the game, we have that A outputted a proof $\pi = (\pi_p, \pi_1, \pi_2)$ that verifies but A is not compliant with the specified policy.

 A choose a policy f with its auxiliary parameters aux, an initial public key ${\tt pk}_0$ and two snapshots from the blockchain ${\tt state}_1, {\tt state}_2.$ Then ${\mathcal A}$ constructs $\pi=$ (π_p, π_1, π_2) which as defined in [Figure 5](#page-29-0) is a ZK-proof for the correct shuffle of the accounts and the relations $R_1(x, w)$, with $x = (\mathsf{pk}_0, \{\# \mathsf{acos}_j, \left[\# \mathsf{acos}_j\right], \{\mathsf{acct}_{ji}\}_{i=1}^{\# \mathsf{accs}_j} \}_{j=1}^2)$ and $w = (sk)$ and $R_2(x, w)$, with $x = (\{\text{act}_{1i}\}_{i=1}^{\#\text{accs}_j}, \{\text{act}_{2i}\}_{i=1}^{\#\text{accs}_j}, \overline{[v]}, \text{aux})$ and $w = (sk, v)$, where v, aux are values that depend on the policy.

The soundness property of the correctness of the shuffle [\[3\]](#page-15-5) prevents the adversary from altering the values of the initial accounts.

From the soundness property of the NIZK argument of the π_1 , we can extract a witness $w^* = \mathsf{sk}^*$ such that $R_1(x, w^*) = 1$. We have that every $\mathsf{pk} \in \{\mathsf{pk}_0\} \cup$ ${ \{ \mathsf{acct}_{ji}.\mathsf{pk} \} }_{i=1}^{\mathsf{Haccs}_j},$ VerifyKP(sk^{*}, pk). Therefore similarly to theft-prevention proof we can prove that if $sk^* \in$ honest then A can be used to break the unforgeability property of UPK scheme. Else if $sk^* \in \text{corrupt}$ then since A wins the game, we have that the opening to the commitment of $\#accs$ is different from the one that resulting from bookkeeping. This trivially breaks the binding property of the commitment scheme.

From the soundness property of the NIZK argument of the π_2 , we can extract a witness $w^* = v^*$ such that $R_1(x, w^*) = 1$. Again since A wince the game the sum of the openings of the commited value of all the accounts that belongs to A is different from the one that resulting from bookkeeping, so this breaks the binding property of the commitment scheme.
