## 10 11 ABSTRACT

12  
13 Waste information is necessary for proper management planning. However, data on  
14 waste generation and management are sometimes not reliable enough, do not exist or  
15 are not useful for the sector. This is due to the high number of waste types and flows,  
16 and actors (producers, managers and administrations), which make data collection and  
17 treatment difficult. Furthermore, data loss occurs because some waste flows have  
18 economic value and return to the second-hand markets without monitoring.

19 The development of a waste information system for a region is more than just about  
20 establishing a routine data collection on waste. It is a way to support the challenges of  
21 decision-making on waste management. These challenges range from strategic issues  
22 of waste management in the national government to the basic challenges of running  
23 local governments.

24 In the Cantabrian region, three indicator sets were defined to constitute the waste  
25 information system: (a) a Basic Indicator Set, which provides an overview of the status  
26 of the generation and management of the main waste streams, giving a national and  
27 international comparative analysis of the situation; (b) a Specific Indicator Set, which  
28 monitors the objectives of the different waste policies, and (c) a Transverse Indicator  
29 Set, which analyses the influence of different economic and social variables on the  
30 generation of specific waste streams.

31 The Waste Information System of the Cantabrian Region has been created using a  
32 specific methodology for developing indicator sets with multiple objectives. This  
33 methodology consists of seven steps: (i) the synthesis, selection of the indicators sets;  
34 (ii) analysis of the system under study and data sources; (iii) evaluation of the  
35 indicators proposed; (iv) application and interpretation; (v) public review, dissemination  
36 and updating protocol; (vi) improvement of indicators sets using SWOT analysis; and  
37 (vii) aggregation of all indicators in an aggregated index.

38 These indicator sets with a total of 27 indicators allow tracking the evolution of  
39 generation and management of waste streams and the achievement of the policy  
40 objectives, establishing a data record, evaluating the data and sources of data,  
41 monitoring proposed action and its effectiveness summarizing large amounts of data  
42 on waste in order to spread it to the public and finally, aggregate all information in a  
43 single index that allows the evaluation of the evolution of all waste sectors in time.

47

## 48 **1. INTRODUCTION**

49

50 Developing a waste information system for a region or a country is more than just  
51 collecting routine data on an environmental issue. It is about facilitating an improved  
52 waste management by providing timely, reliable information to the relevant role-  
53 players. Such information is crucial for planners, authorities, social organizations,  
54 academic institutions, and the general public, and it is a valuable input for assessment  
55 purposes, for public policies and for the implementation of programs and projects. It is  
56 a means of supporting the waste governance challenges, ranging from strategic waste  
57 management issues at national government to basic operational challenges at local  
58 government (Godfrey, 2008; Rojas-Calderas and Corona, 2008; Wen et al., 2009).

59 Solid waste management involves technical, socioeconomic, legal, ecological, political  
60 and cultural components (Miafodzyeva, et al., 2013). Several models using a variety of  
61 methods and tools to support decision making in the MSW have been developed  
62 (Morrissey and Browne, 2004; Chang et al., 2011).

63 Indicators and indices (aggregated indicators) are important tools that assist decision-  
64 makers in formulating, implementing and assessing models, global strategies and  
65 policy measures for a sustainable MSW management plan (Yabar et al.,2012). They  
66 are a means to capture the complexity and transform it into small amounts of key  
67 information and therefore help non-technical specialists to make use of complex data  
68 sets (Bell and Morse, 2013). Besides, indicators can be used to track progress over  
69 time, to compare characteristics between one or more systems, and they can be used  
70 as criteria in decision making tools (EEA, 2003; Giljum et al., 2011).

71 Theoretical conditions that the indicators must fulfil depend mainly on the type of  
72 indicator and the purposes for which it is defined (Dewulf and Van Lengenove, 2005;  
73 EEA, 2004; Suttibak and Nitivattanon, 2008). Among the multitude of possible  
74 requirements it seems reasonable to highlight the following (Cifrian, 2013): (i) Relevant:

75 related to goals; (ii) Credible: Based on complete and accurate data; (iii) Functional:  
76 Useful in decision-making; (iv) Quantifiable: Reasonable ratio cost – effectiveness; and  
77 (v) Comparable: Obtained at different spatial and temporal scales. Obtaining enough  
78 high quality data is a key issue that affects the whole methodological process of  
79 designing a set of indicators.

80 Currently, quantities of waste data are widely available and regularly published  
81 internationally by the European Environment Agency, Eurostat, the OECD and other  
82 relevant environmental agencies. However, there are significant limitations to this type  
83 of reports, such as the heterogeneity of sources of waste data, the variability in  
84 terminology to define each kind of waste, the lack of detailed data at regional and local  
85 level, the lack of information at operating level and the lack of information on the  
86 financial aspects. This lack of information is the main problem encountered when  
87 starting up an environmental information system, especially at regional level. To  
88 overcome the limitations in waste information, different authors propose agreed  
89 definitions and estimation methods, as well as the creation of platforms and  
90 observatories for information exchange and to share experiences between different  
91 geographical levels (De Clercq and Hannequart, 2010; Rodriguez et al., 2008; Wen et  
92 al., 2009).

93

94 The objective of this paper is the development of an environmental information system,  
95 which can be used as a decision-making tool for stakeholders. This environmental  
96 information system has been defined to comply with a threefold purpose: First, to give  
97 an overview of the status of the environmental issue studied; in this manner a  
98 comparison of the status and progress with other regions is allowed, obtaining a  
99 comparative analysis of the situation and sharing results. Second, monitoring the  
100 different environmental policy objectives. The third objective is to analyse the  
101 relationship between the environmental issue and social or economic variables. For  
102 these objectives, three sets of indicators have been proposed: Basic Indicators Set  
103 (BIS), Specific Indicators Set (SIS), and Transverse Indicators Set (TIS).

104 To obtain this environmental information system, a complete and integrated  
105 methodology has been developed; each step of the methodology is detailed in Section  
106 2 of the present paper. Section 3 shows the application of the methodology to the  
107 Regional waste system of Cantabria, Spain, which allows to obtain aggregated indexes  
108 to analyse the actual situation and propose improvements in the waste management  
109 field.

110

111

## 112 2. METHODOLOGY DEVELOPED TO OBTAIN DIFFERENT INDICATORS SETS

113  
114 The methodological procedure of developing a set of indicators must ensure an  
115 adequate definition of objectives, consistent development and a high degree of  
116 applicability. Often, the method for selecting indicators is based on historical practices  
117 or intuitive assessment of experts, and the admission of the indicators depends on the  
118 degree of individual compliance with the criteria, regardless of whether the set of  
119 indicators responds to the environmental issue to be monitored (Bossel, 2002; Donnelly  
120 et al., 2007; Niemeijer and Groot, 2008). In the present paper an integrated  
121 methodology has been developed, in order to improve these historical practices, which  
122 in most cases does not detail the method used for the selection of indicators. This  
123 methodology is applied to obtain different sets of indicators according to the objectives  
124 proposed (Figure 1). It is a comprehensive process that includes all three sets of  
125 indicators. The first step of the methodology is particular for each set of indicators,  
126 related with its purpose, but most of the steps are common to all sets and can be  
127 applied in an integrated way. Each step of the methodology is detailed.

### 128 129 **Synthesis of Indicators Sets**

130 The synthesis step consists of selecting of the indicators that will form the indicators set  
131 using specific criteria. Criteria used vary in function of the objective of the indicator set,  
132 as Figure 2 shows. In the first case, the Basic Indicators Set, the indicators selected  
133 are those, which allow the comparability of results with other regions. The criterion  
134 used is that the indicators have to be widely used (Haghshenas and Vaziri, 2012). For  
135 the Specific Indicators Set, the starting points are the objectives outlined in  
136 environmental policies, and the indicators selected are those that allow monitoring the  
137 environmental policy issues behind these objectives (ETCWMF, 2002); the indicator  
138 selection is driven by questions that the indicators are supposed to answer (Li, et al.,  
139 2009). It is necessary to know the relation between the environmental issue and  
140 economic or social variables for the Transverse Indicators Set. The methodology to find  
141 the socio-economic variables associated with the environmental issue under study is  
142 specific since it depends on the characteristics of this issue. You cannot define a  
143 general method, although a common step applicable to any environmental issue is  
144 conducting a literature review. However the use of general transverse concepts as  
145 Intensity and eco-efficiency, can guarantee the homogeneity between sustainability  
146 concepts and the significance of the transversal indicators for each application. Hence,  
147 before the review, the variables that meet the criteria are selected (Sébastien and  
148 Bauler, 2013).

149 **Analysis of Available Data**

150 The analysis stage involves the qualitative and quantitative study of the environmental  
151 issue under study. It is also necessary to know which data of the different variables of  
152 the activity or sector studied are available. The goal is to find all sources of available  
153 data on studied issue, its characteristics, and developing a record of data sources for  
154 each indicator.

155

156 **Evaluation of Indicators**

157 The indicators are evaluated under different criteria. Applying these criteria to define  
158 some questions (or sub-criteria) and providing a score depending on the answers (a  
159 maximum value of 18 points), the viability and feasibility of the indicators can be  
160 labelled. Only indicators with a score higher than 50% of the maximum value, i.e. 9  
161 points, are considered with quality enough to be applied in the next step. This  
162 assessment shows the weaknesses associated with a lack of available data (EEA,  
163 2005; Yli-Viikari et al., 2007). Criteria, sub-criteria and scores used are shown in Table  
164 1.

165

166 **Application, Interpretation and Evaluation of the results of the indicators**

167 The application of the indicators makes necessary to calculate specific variables such  
168 as rates or ratios. The progress with time is represented graphically and, then, an  
169 analysis is performed to define the trends. All this information is included in a fact  
170 sheet, which also includes information, such as applicable rules or guidelines that can  
171 help to give an overview of the situation. The created indicators fact-sheet also  
172 specifies the characteristics of its data, the calculation method, its variables and the  
173 information sources.

174 For the evaluation of results, a criteria definition is required in accordance with the  
175 normalization criteria defined (aggregation step). The criteria for the evaluation and  
176 normalization have been defined taking into account the characteristics of each set  
177 (Figure 3) (OECD, 2002; 2008; Singh, et al., 2009). For BIS, the ranking method is  
178 used evaluating the situation of the region in a comparative way, so that the situation of  
179 the region, for this indicator, is represented in function of the position in the ranking  
180 (Greene and Tonjes, 2014). Although ranking is the simplest normalisation technique,  
181 this method is not affected by outliers and allows the performance of countries to be  
182 followed over time in terms of relative positions. Some examples that use ranking  
183 include: the information and Communications Technology Index (Fagerberg, 2001) and  
184 the Medicare Study on Healthcare Performance across the United States (Jencks et  
185 al., 2003). For SIS, the distance to a reference method is used, evaluating directly the

186 degree of achievement of the policy objectives. This technique measures the relative  
187 position of a given indicator from a given reference. This could be a target to be  
188 reached in a given time frame (Ronchi et al., 2002). Many indexes use this technique  
189 for the evaluation and normalization of the indicators, such as the Eco-indicator 99 (Pre  
190 Consultants, 2004), the Index of Environmental Friendliness (Puolamaa et al., 1996) or  
191 the Environmental Policy Performance Indicator (Adriaanse, 1993). Finally for TIS, the  
192 method closest to its characteristics is the min-max, which normalises indicators to  
193 have an identical range [0, 1] by subtracting the minimum value and dividing it by the  
194 range of the indicator value. The most important indexes that apply this technique are  
195 the Human Development Index (United Nations Development Programme, 1990), the  
196 Technology Achievement Index (Nasir et al., 2011), and the Composite Sustainable  
197 Development Index (Kranjnc and Glavic, 2005)

198

### 199 **Public Review, Dissemination and Update**

200 Each set of indicators created is presented to the potential users and different  
201 stakeholders in order to achieve an in depth review. Criteria closest to users become  
202 more relevant, although conceptuality and aspects of validity of the indicator are still  
203 applicable at this stage. After public review, a new round of internal review and specific  
204 stakeholder and expert consultations starts. At this stage the criteria related to the end  
205 use of indicators become priority. The result of this step is a set of indicators  
206 representative of social concerns. Noteworthy is the importance that acquires the  
207 participatory aspects in this process (Bringhenti, et al., 2011). The indicators set will  
208 succeed only passing through the proper process of socio-political and institutional  
209 assessment.

210 The main objective of the indicators sets developed is to show the relevant information  
211 to managers, politicians, and general public, so an important step in the methodology is  
212 the dissemination of results.

213 It is also necessary to update all the indicators developed using data from the previous  
214 year. Beside the data, it is important to know possible changes in legal frameworks or  
215 any other aspect of concern that may have occurred during last year that can influence  
216 in the way of the information is managed or the objectives included in the indicators.

217

### 218 **Continuous Improvement (SWOT Analysis)**

219 SWOT analysis integrates internal resources of an indicator (Strengths/Weaknesses)  
220 and external environment analysis (Opportunities/Threats) under a classic strategic  
221 analysis tool for strategic management (Yang, 2010). Applying this analysis, a wide  
222 range of improvement tactics applicable to the indicators is obtained (Handakas and

223 Sarigiannis, 2012). Overcoming each of these weaknesses, it is possible to achieve a  
224 continuous improvement of the global information system.

225

### 226 **Aggregation of indicators**

227 In this step, all indicators from each set are normalized and aggregated in a single  
228 index. Methods proposed for the normalization of indicators are according to the criteria  
229 used in the evaluation, which have been shown in Figure 3. Once the values of the  
230 indicators are normalized in the range 0-1, it is necessary to select the methods of  
231 weighting and aggregation.

232 It is recognised that reducing assessment to a single dimension misses many of the  
233 cross-linkages and ultimately leads to poor decision-making (Paracchini, et al., 2011).  
234 To minimize this problem, the tool “Dashboard of Sustainability” (DS) was applied to  
235 aggregate the indicators to show jointly the results of each indicator, their relative  
236 importance (weight) and the aggregated index in the same figure. This tool provides  
237 visual results which are easier to understand by the stakeholders (Hardi and DeSouza-  
238 Huletey, 2000; Hardi et al., 2002; JRC, 2007).

239 The Dashboard of Sustainability organizes the assessment of information into two  
240 levels represented by the following concentric rings (Scipioni et al, 2009). In this work,  
241 these two levels represent: (i) the outer ring, the individual indicators used, with the  
242 same weight inside each set of indicators; (ii) the inner circle synthetic indexes, which  
243 integrate multiple indicators into a single measure.

244 The indexes allow a temporal analysis of the results. The main restriction of this  
245 methodology is that it is necessary that all data of indicators for all studied years are  
246 available. If the data of one indicator were unavailable the accuracy of the index to  
247 track the system over years decreases.

248 The obtained indexes allow comparison between different cases studies too due to the  
249 indexes are based on relative measures. It is important to always keep in mind what  
250 are comparing with these indexes. The Basic index represents the situation of the case  
251 study with regard to others; the Specific index represents the degree of achievement of  
252 the policy objectives, regardless of how ambitious that policies are; and the Transversal  
253 index represents the efficiency with respect to the socio-economic situation.

254 In recent years, DS is becoming a tool commonly used by the scientific community to  
255 analyse the dimensions of sustainable development through the use of indicators and  
256 aggregate indices. DS is a tool internationally accepted to compare progress in  
257 sustainable development between countries and aids decision-making and  
258 communication as well as dissemination of results. Furthermore, DS is a very versatile  
259 tool that can be applied at regional or even urban levels (Picollo et al, 2003; Scipioni, et

260 al, 2009). The tool has also been applied to a strategic environmental assessment of  
261 the waste plan of a region (Federico et al., 2009).

262 As a result of the application of this methodology three sets of indicators are obtained.  
263 The first one (BIS), with general indicators, that allows comparison with other regions;  
264 the second set (SIS) with more specific indicators, that allows monitoring of  
265 environmental policy objectives; and the third set (TIS), with eco-efficiency indicators,  
266 that measures the influence of the socio-political situation on the environmental issue.  
267 In addition, three aggregate indices, one for each system, which allows studying global  
268 trends over time for each of these aspects, as well as a global index that summarizes  
269 all information obtained.

270

### 271 **3. APPLICATION TO THE REGION OF CANTABRIA**

272

273 Cantabria is a northern Spanish region, ranging from the Cantabrian Mountains to the  
274 waters of the Cantabrian Sea, covering an area of 5,326 km<sup>2</sup>. The population is nearly  
275 600 000 inhabitants, which represents only the 1.26% of the Spanish population. The  
276 GDP of the region represents 1.25% of the Spanish GDP, and it is mainly contributed  
277 by the service sector and the industrial sector which represent 81% of the regional  
278 GDP. 92% of the enterprises of the region have less than 5 employees (ICANE, 2014).  
279 The production of municipal waste in the region reaches values of 579 kg per  
280 inhabitant/year, while the national average is 500 kg per inhabitant/year. In the case of  
281 industrial waste, the value of generation in Cantabria is 836 kg per inhabitant, and 10%  
282 of it is hazardous waste. The national average is 1075 kg per inhabitant, and less than  
283 3% of it is hazardous waste (Cifrian et al., 2012; 2013).

284 Figure 4 shows the proposed policies in different legal frameworks on waste  
285 management, which are mandatory in the region of Cantabria. These policies propose  
286 a series of objectives that must be tracked. The objectives proposed in a broad legal  
287 framework (International, EU) have been adopted into the narrower legal frameworks  
288 (National, Regional); particularly the EU regions must develop and ensure the  
289 implementation of regional instruments in order to meet the environmental Municipal  
290 Solid Waste Management (MSWM) objectives and targets. In this context the proposed  
291 methodology has been applied, obtaining better elaborated information in each step.

292

#### 293 **3.1 Obtaining the indicators of each set (Synthesis Step)**

294 The synthesis step aims to select indicators that will form each set. Each set of  
295 indicators has a particular synthesis methodology since they follow different objectives.

296 In the case of BIS, a thorough review of the environmental agencies that use indicators  
297 to show the corresponding waste data has been carried out. The review has covered  
298 the information posted on Web sites of the most important organizations in the  
299 dissemination of information in the environmental field at different geographical levels:  
300 (i) Municipal: Local Agenda 21 developed in different Spanish municipalities, (ii)  
301 Regional: Environmental Departments of different regional Governments and Statistical  
302 Offices of them; (iii) National: the Ministry of Environment, the Sustainability  
303 Observatory and the National Statistical Office; and (iv) International: the European  
304 Environmental Agency (EEA), the European Statistical Office (EUROSTAT), the  
305 Organisation for Economic Co-operation and Development (OECD) and the United  
306 Nations (UN). A total of 57 sources have been enquired.

307 Once the review has been completed, the management of information consists in  
308 grouping indicators with similar information, although the indicators proposed were not  
309 exactly the same. The main criterion for selecting indicators is its level of usage in  
310 different geographical areas (Figure 5). Amongst all indicators that meet this criterion,  
311 those that fulfil the rest of the criteria (to be relevant, reliable, functional, quantifiable  
312 and comparable) are selected. The final indicators of BIS are shown in Table 2.

313 For the synthesis of the SIS, the starting points are the objectives proposed in the  
314 Regional legislation and plans. To avoid a high number of indicators, first of all the  
315 objectives that can be tracked by the same indicator need to be gathered by grouping  
316 objectives about the same type of waste or type of management.

317 Policy questions related to the objective of the waste plan must be associated in  
318 addition to the environmental aim for which this objective was formulated. For example,  
319 for the objective “Creating a distribution plan of manure and slurry” the policy question  
320 proposed is: Are the manure and slurry properly managed?, and the indicator defined  
321 is “Management of manure and slurry”.

322 In this way, applying this method to each objective or group of them, 16 indicators have  
323 been obtained to monitor a total of 28 objectives of the Regional Waste Plan (Table 2).

324 For the synthesis of TIS, a selection of variables with influence on the generation of  
325 waste has been elaborated. To begin, two waste streams, municipal solid waste and  
326 industrial waste were selected because they are large flows that include much of the  
327 waste generated in the Cantabria Region. Although in this work only global flows have  
328 been studied, this method can be used to analyse more specific waste flows with very  
329 specific characteristics. An example is the case of WEEE (Waste Electric and  
330 Electronic Equipment), affected by specific variables such as lifetime or growing

331 consumption in technological items; another example is the CDW (Construction and  
332 Demolition Waste), affected by the large real estate crisis and the increasing  
333 regulations on the management of these wastes.

334 A literature review to select the variables which influence the generation of municipal  
335 solid waste has been conducted. The analysis of previous literature references had  
336 focused, on the one hand, on publications of agencies related to MSW management,  
337 such as Integrated Management Systems or technical reports from different  
338 institutions, such as municipalities, regional governments and environmental groups,  
339 among others. On the other hand it focused on scientific articles, highlighting those  
340 related to the modelling of the generation of solid waste. Once the variables are  
341 collected, it is necessary to classify them. Salhofer et al., (2007) describe a model for  
342 waste generation analysis based on input-output models. In this model, two flows of  
343 materials are defined, one to the waste generator (Input) and one from it (Output).  
344 Therefore, using this model a descriptive characterization of waste streams through the  
345 stages of the product life cycle is possible and each selected variable is classified in  
346 this framework (Niemeijer and Groot, 2008). For this purpose, three stages have been  
347 described, the production of goods and services, the consumption of them and the  
348 collection and treatment of waste (Figure 6). Variables that have been included in the  
349 indicators are those that accomplished three criteria: well defined, quantified, and  
350 independent. The variables selected are: population, number of households, population  
351 density, employment, purchasing power, life expectancy, GDP, and average  
352 expenditure.

353 For the generation of industrial waste, related variables are those associated with the  
354 sector in which they are generated, being able to classify data by sector or globally. For  
355 the selection of economic and social variables associated with each sector, tables of  
356 Regional Accounting (ICANE, 2014) have been used. In these tables, the key  
357 economic variables of the region are published, and the three most representative of  
358 them have been selected: GDP (Gross Domestic Product), employment (jobs) or  
359 number of companies.

360 The indicators proposed for TIS are efficiency ratios (Wang and Côté, 2011).  
361 Generation of waste is divided by the different variables selected, obtaining values that  
362 can be useful for cross-sectorial comparability and for analysing temporary evolutions  
363 (Ramadan and Sherif, 2008).

364

### 365 **3.2 Defining the best sources of data (Analysis Step)**

366 In this step, a deep analysis of waste management systems of different waste flows  
367 has been carried out and the sources of data with a higher reliability have been  
368 selected.

369 In the first step, the implementation of waste management activities in the Cantabria  
370 region is studied and different available records and the potential sources of data are  
371 gathered (Figure 7). In the second step, available data are compared, selecting best  
372 data sources, and creating a data catalogue with the information we have gathered.

373

### 374 **3.3 Evaluating the indicators and the data (Evaluation Step)**

375 The synthesized indicators and the selected data are evaluated according to the criteria  
376 and sub-criteria showed in Table 1. Total and partial scores obtained by each indicator  
377 are represented in Figure 8. The maximum value that an indicator gets in the scoring is  
378 18. It was established in this work that those which obtain a value lower than 50% of  
379 the maximum value, 9 points, have a low potential for development and they cannot be  
380 applied in the short term.

381 As can be seen in Figure 8, Basic Indicators present high quality with more than 14  
382 scoring points for all them. These indicators have the best score compared to other  
383 sets, both temporally (comp1) and geographically (comp2). About the Specific  
384 Indicators, from 16 indicators proposed, there are 4 without enough quality to be  
385 developed in the short term (SI6, SI8, SI9 and SI10). In the case of TIS, the scoring is  
386 applied separately to the indicators TI4, TI5 and TI6 for Hazardous Waste (HW) and  
387 Non Hazardous Waste (NHW), due to their different data sources. Those related with  
388 Non Hazardous Waste do not have score enough to be applied.

389

### 390 **3.4 Main Results obtained about waste management in the Cantabrian Region** 391 **(Application, Interpretation, and Evaluation of results Step)**

392 With the indicators of each set selected and data sources defined, the application and  
393 interpretation of results have been carried out. The application involves defining the  
394 formula for calculating the indicator, and all the individual variables it composes.  
395 However, the application is not only about applying data to the indicators, it is also  
396 about developing the data sheets of the indicators. These sheets include information  
397 that allows the interpretation of the evolution of the indicator, and evaluate the results in  
398 a legal, temporally and geographical framework. Furthermore, the graphical  
399 representation of the indicator and its variables is discussed and selected, providing  
400 intuitive and easy knowledge of the current situation, the evolution over the years

401 studied and the comparison to the objectives of each indicator. The main results  
402 obtained in Cantabria are summarized in Table 3.

403 The interpretation and evaluation of the results shown by the indicator is performed  
404 through a regional key (comparison with all Spanish regions), a legal key (current  
405 situation with respect to the policy objectives), and a temporal key (analysis of time  
406 trends and possible predictions of behaviour). In this sense, the evaluation of results  
407 consists in applying the criteria of Figure 3: (i) for BIS, depending of the position in the  
408 ranking of the results obtained by all Spanish regions, (ii) for SIS, the degree of  
409 achievement of the objectives proposed in the regional Waste Plan, and (iii) for TIS, the  
410 degree of decoupling of waste generation and socio-economic variables with respect  
411 the previous year.

412 Table 3 shows a good global situation of the waste sector in the region (green icons),  
413 (i) with respect to other regions, especially in waste management (BIS); (ii) achieving  
414 the policy objectives (SIS), and (iii) the decoupling of waste generation and economic  
415 and social development (TIS). For indicators with yellow and red icons a set of  
416 improvement proposals must be defined.

417

### 418 **3.5. Dissemination of indicators and results and establishment of a protocol data** 419 **update (Public Review, Dissemination and Update step)**

420 The developed indicators were sent to different stakeholders of the region in order to  
421 comply with the public review (Environmental Department of the Regional Government  
422 or waste managers of the region, among others). Afterwards, the indicators were  
423 presented in different environmental forums. In the case of the Specific Set developed  
424 for monitoring policies, the indicators were published, together with the Regional Waste  
425 Plan, for public review and any citizen could suggest changes.

426 The comments and suggestions received were mainly related to the contents of the  
427 indicators and not about the definitions of the indicators themselves. There were  
428 comments about the management of any waste flows, or inquiries for more  
429 explanations about the data sources of recycling. All comments were taken into  
430 account, studied, and included in the indicators fact sheet.

431 Moreover, an essential activity in the management of the environmental information  
432 system (EIS) is the dissemination of the indicators developed. The information  
433 developed has to reach all interested people, so it must be published in a simple,  
434 accessible way and as widely as possible. For that purpose, the web page of the EIS  
435 was published in 2006 and it became in the main dissemination tool (FPW, 2006).

436 In addition to the website, many activities have been undertaken in order to  
437 disseminate the information: publication of leaflets, booklets, press releases, digital  
438 newsletters, mailings and presentations in some environmental forums.

439 Finally, a protocol for updating the indicators using data from the previous year has  
440 been developed. The first activity is to track changes in waste management, such as  
441 authorizations for new integrated management systems or waste managers or the  
442 opening or closing of management facilities. All these actions can change the way  
443 information is managed and the data sources. The second activity is to track the  
444 evolution of the legal framework, updating the new proposed objectives if necessary.  
445 The third activity is to request all information about the data sources, sending the  
446 requesting form to the different organizations. All information gathered in this way  
447 allows the indicators to be updated.

### 448 **3.6. Improvement of the indicators and results**

449  
450 A SWOT analysis is applied on all the indicators which have not presented enough  
451 quality in the evaluation step, and over the indicators which were proposed to be  
452 improved in the Application and Public review steps (Figure 1). The SWOT analysis  
453 consists in a systematic assessment of all activities with influence on the information  
454 management. These activities are classified as strengths, weaknesses, opportunities  
455 and threats, identifying the internal and external factors that are favourable and  
456 unfavourable to achieve the proposed objective. In order to increase the quality of the  
457 indicators, it is necessary to propose actions related to the weaknesses founded, so  
458 that an improvement in these activities can have a high impact on the quality of the  
459 indicators. The main weaknesses found were related to the absence of one or more of  
460 these elements: specific legislation, specific plans, obligation to provide periodic reports  
461 to the authorities, regional data records, computerization data, grants to allow the  
462 implementation of correct waste management systems or information campaigns.

463 For each of these weaknesses, a series of lines of action must be proposed. They must  
464 be operational and potentially improve the current situation of some of the indicators  
465 developed. They generally involve the implementation of changes in varying degrees  
466 and may involve particular resourcing and development of specific plans and  
467 regulations. Lines of action proposed include the creation of specific plans, establishing  
468 new management models, offering grants or economic agreements, information  
469 campaigns and developing data records.

470

### 471 **3.7 Aggregated indicator for evaluating the situation and trend of waste** 472 **management in the Cantabrian Region**

473

474 The last methodological step is the aggregation of the indicators (Figure 1). First of all,  
475 the normalization of the values of the indicators is performed using ranking, distance to  
476 a reference and min-max methods respectively for BIS, SIS and TIS.

477 The weighting of the indicators used equals their weight inside each set (BIS, SIS,  
478 TIS), and the weight for each of the indicators sets to obtain the global index.

479 The Dashboard tool performs the aggregation of indicators by multiplying the value of  
480 each indicator with the weight coefficient and summing up each of the indicators that  
481 will form part of the index. The periods considered in the study are 2006 and 2010 as  
482 the years of approval and finalisation of the Cantabrian Waste Plan, and 2008 as the  
483 central year.

484 Figure 9 shows the results obtained by every indicator. The situation of the aggregated  
485 indexes, Basic Index (Figure 9a), Specific Index (Figure 9b) and Transverse Index  
486 (Figure 9c) are displayed in central circles. These indexes are obtained through the  
487 aggregation of the indicators around them. A global index called “Cantabrian Waste  
488 Overview” is obtained by aggregating the Basic, Specific and Transverse indexes  
489 (Figure 9d).

490 The evolution of aggregated indices during the study period is a continuous  
491 improvement of the situation, especially regarding compliance with the regulations  
492 (Specific Index), as in the case of the transversal index, showing the continued  
493 decoupling of waste generation and productive activities and social welfare. Compared  
494 to other Communities (Basic Index), no significant changes are shown in the studied  
495 period.

496 The global index “Cantabrian Waste Overview” reflects a continuous improvement  
497 during the period 2006-2010. The analysis of these results reflects in a simple,  
498 understandable and complete way the evolution of the global environmental situation in  
499 the waste area in Cantabria.

500

## 501 **4. CONCLUSIONS**

502

503 This paper summarizes the design of a waste information system based on three sets  
504 of complementary indicators which provide information on: (i) The current situation of  
505 the region and the trend followed throughout time in a compared way; (ii) the level of  
506 compliance with the waste policy objectives for European, national and local legal

507 frameworks, and (iii) the influence of different economic and social variables on  
508 generation trends of specific waste streams.

509 To obtain the environmental information system, a novel methodology to develop  
510 indicator sets has been designed. The proposed methodology represents a  
511 breakthrough in the field, for his aforementioned triple vision and because it proposes  
512 an objective method for the selection and evaluation of indicators, issues that hitherto  
513 had given them a relatively minor importance. This methodology can be applied to  
514 whatever topic and scale both temporal and geographical. Three sets of indicators  
515 have been designed according to the objectives proposed in the synthesis step; a basic  
516 set with 6 indicators, a specific set with 16 indicators, and a transversal set with 5  
517 indicators. Furthermore, a quantitative, objective method of evaluation of the indicators  
518 is included in order to show the quality of the indicators and those that do not have  
519 enough quality have been rejected: 4 indicators in the specific set and 3 in the  
520 transversal set, all of them because there are not any reliable data about these waste  
521 streams. Finally, the indicators are aggregated to present the global situation, without  
522 losing the information of each individual indicator using a “Dashboard of Sustainability”  
523 tool.

524 From the application of this novel methodology to the Cantabrian waste sector, it is  
525 important to highlight that there are satisfactory trends in the studied years, with a high  
526 degree of compliance with waste policy objectives, especially those related to waste  
527 management, and showing the continued decoupling of waste generation and  
528 economic development and social welfare. Using the individual indicators, activities are  
529 detected on which efforts should be focused in coming years, mainly related to the  
530 minimization of the generation of different waste streams. Through the aggregated  
531 index, the overall situation of the generation and management of waste at the regional  
532 level has be analysed, obtaining a continuous improvement over the years studied.

533

Table 1. Criteria and sub-criteria with their score to evaluate indicators.

CRITERIA	Questions or Sub-criteria	Scoring
<b>Relevant</b> Related to goals	Relev1. Is the indicator linked to policy targets, objectives or legislation?	0= No 1= Yes, indirectly 2= Yes, directly
	Relev2. Could the indicator provide information that is useful for policy decisions?	0= No 1= Yes
<b>Credible</b> Based on complete and accurate data	Cred1. Are the data complete?	0 = No data record 1 = Data from various sources 2 = Data from a single source
	Cred2. Are the data accurate?	0= No data record 1= Estimates 2= Direct measurement
<b>Functional</b> Useful in decision-making	Func1. Could the indicator provide clear and easy information?	0= No 1= Interpretation requires prior knowledge 2= Direct interpretation
	Func2. Is the indicator sensitive to changes?	0= Slow; delays the response 1= Fast; Immediate response
<b>Quantifiable</b> Easiness measure	Quant1. Are the data easily accessible?	0= No 2= Yes
	Quant2. What is the format of the data?	0= No data record 1= Paper record 2= Electronic record
<b>Comparable</b> Obtained at different spatial and temporal scales.	Comp1. Are time series are available?	0= No data record 1= No, only data points 2= Complete data record
	Comp2. Does the indicator have good geographical coverage?	0= No 1= Comparable across Municipalities or Regions 2= Comparable across Municipalities and Regions

BI1. Generation of MSW	SI1. Generation of waste	TI1. Social variables related to generation of Municipal Solid Waste
BI2. Treatment of MSW	SI2. Treatment of Construction and Demolition Waste	TI2. Eco-efficiency of Municipal Solid Waste Generation
BI3. Recycling Rate of Paper and cardboard and Glass	SI3. Treatment of Used Tyres	TI3. Intensity on waste (HW and NHW) of the company
BI4. Recovery rate of plastic, metal and wood packaging waste	SI4. Production and destination of sewage sludge	TI4. Eco-efficiency of the generation of waste (HW and NHW) of the company
BI5. Production and destination of sewage sludge	SI5. Packaging Waste Collection and recycling by an Integrated Management System	TI5. Intensity on employment of the generation of waste (HW and NHW) of the company
BI6. Management of Hazardous Waste	SI6. Treatment of Waste Electrical and Electronic Equipment	
	SI7. Quantity of oil-wastes collected at Municipal Collection Points	
	SI8. Management of manure and slurry	
	SI9. Contaminated soil remediation	
	SI10. Excavation Land Management	
	SI11. Rate of sale of compost	
	SI12. Energy from waste	
	SI13. Rate of landfill of biodegradable waste	
	SI14. Disposal in landfills	
	SI15. Installation of Municipal Collection Points	
	SI16. Installation of Landfills

791  
792

Table 3. Main Results obtained in the application, interpretation and evaluation of the three sets of indicators in the Cantabria Region during 2011.

Ind. Code	Application	Interpretation	Evaluation (2011)
BI1	Sum of the quantities of MSW collected in different ways: selective, bulk, clean points, voluminous.	Change in production trend in 2008, begins to decrease MSW production due to change in consumption patterns. Fourth region in MSW production rate.	
BI2	Percentages of the amounts of MSW managed in each treatment over the total generated: recycling, composting, energy recovery and landfilling.	Decrease in the quantities of MSW managed in landfill in favour of techniques such as incineration with energy recovery, recycling or composting. Second region in MSW valorisation rate that includes the recycling, composting and energy recovery.	
BI3	Ratio of the amount recycled divided by the amount consumed The amount recycled is calculated as the sum of the amounts separately collected and recovered from mixed waste.	Continuous increase in the amounts recycled, up to 60% for glass and 70% for paper and cardboard Fourth region in glass, and paper and cardboard recycling.	
BI4	Ratio of the amount recovered divided by the amount consumed (for each material: plastics, metals and wood).	Continuous increase in the amounts recovered, up to 40% for plastics and near 100% for metals and wood packaging waste. Fourth region in plastic, metal and wood packaging waste recovery.	
BI5	Total quantity of Sewage Sludge (SS) produced and Percentages of the amounts of SS managed in each treatment over the total generated: used in agriculture, incinerated, and landfilled.	Change in production trend in 2007. Decreasing SS production due to improvements in sewage treatment stations. Changes in management model: from total landfilling to use in agriculture as a fertilizer. Third region in production of sewage sludge rate.	
BI6	Sum of the quantities of Hazardous Waste (HW) send by each producer of HW to each manager of HW.	Decrease in the HW production, due to an industrial production drop in the region. Second region in hazardous waste production rate.	
SI1	Sum of the quantities of Hazardous Waste (HW) send by each producer of HW to each manager of HW and quantities of Non Hazardous Waste (NHW) treated in the region.	General decrease in HW and NHW produced in the region. The objective, Stabilization of waste generation rates for each sector, is reached by all sectors: municipal, special, industrial and primary sector, but it is not enough to achieve the objective for municipal waste of reduce the generation to 2003 level.	
SI2	Percentages of the amounts of Construction and Demolition waste (CD) managed in each treatment over the total generated: Recycling, environmental restoration, and landfilling.	Changes in management model: from total landfilling and environmental restoration before 2010 to reach a rate of recycling over 95% after 2011.	
SI3	Percentages of the amounts of Used Tyres (UT) managed in each treatment over the total generated: Recycling, environmental restoration, and landfilling.	Main treatment for UT is recycling, decreasing the percentage of UT that were recycled between 2008 and 2011. The second treatment is energetic valuation, followed by reusing and landfilling. The objective of recycling more than 25% is widely accomplished.	
SI4	Percentages of the amounts of SS managed in each treatment over the total generated: used in agriculture, incinerated, and landfilled.	The objective of use in agriculture more than 95% of SS produced, has been accomplished since 2010.	
SI5	Quantities of each kind of packaging waste (glass, paper and cardboard, packaging, phytosanitary packaging, and medicines packaging) managed by each Integrated Management System (Ecovidrio, Ecoembes, Sigfito and Sigre).	Quantities managed of each packaging waste have increased with time, so the objective of increasing the packaging waste managed has been achieved.	
SI7	Quantity of oil wastes collected in clean points (vegetable used oil and mineral oil wastes).	Quantities of both oil waste have increased in the period 2005-2010, so the objective is achieved.	
SI11	Rate of sale of compost: quantity of compost produced divided by quantity of compost sold.	Rate of sale of compost is near 100% of compost produced, so the compost produced has enough demand and the objective is achieved.	

SI12	Sum of the energy produced from biogas of landfill and incineration of MSW.	Total power generated is around 97.9 million of kWh, and this power has slight decreased last years due to a drop in the MSW managed in this facilities.	
SI13	Rate of disposal of biodegradable waste in landfills over biodegradable waste generated identified.	Rate of disposal has decreased from 100% in 2001 to 19% in 2011. It is mainly due to the implementation of the compost production facility, and the SS drying plant.	
SI14	Amount of waste disposed in each landfill.	Large decrease in the amount of waste deposited in landfills in the region, both non-hazardous waste and municipal waste.	
SI15	Installation of Recycling points in municipalities with more than 5000 inhabitants	Only one of the 20 municipalities with more than 5000 inhabitants of the region, have not got a recycling point in its area of influence.	
SI16	Number of operating landfills in the region.	Now, there are two landfills in the region, one for Municipal Waste and other for Non Hazardous Waste. The other three existing landfills have been closed until 2010.	
TI1	Graphical representation of social variables that influences Municipal Waste generation: population, number of homes, employment, population density, or life expectancy.	The generation of MSW has decreased in the period 2006-2010, and the rates of MSW generation by inhabitant or home have decrease too. However, the rate of MSW generated by employed has decreased, due to lost of employment in the region in that period. The study of the relation of variables like population density or life expectancy with MSW generation shows no change with time.	
TI2	Eco-efficiency ratios: Economic variables that influence Municipal Waste generation (like consumption, production of goods and services or purchasing power) divided by the MSW production.	Eco-efficiency ratios respect of consumption or purchasing power, have increased in the period studied, due to changes in the consumption patterns. However the ratio with the production has an irregular trend due to the changes in this variable in an economic crisis time.	
TI3	Quantity of Hazardous waste generated per company.	The amount of waste generated by company has decreased, from 3.36 t/company, in 2005, to 1.47 t/company, in 2011.	
TI4	Value of goods and services produced, measured as Gross Value Added, per tonne of Hazardous waste generated.	The eco-efficiency of HW generation has increased, from 83,250 Euros/t, in 2005, to 211,130 Euros/t, in 2011.	
TI5	Employment per tonne of Hazardous waste generated.	The Intensity in employment of HW generation has increased too. From 2.08 employs/t, in 2005 to 3.91 employs/t in 2011.
