Consider mathematical programming:

- LP, MIP, QP (...) models of many interesting problems
- Many theoretical tools for analyzing these models
- General, computational solvers complement the theory

Now consider game theory, especially in the context of our focus today on sponsored search auctions:

- Expressive models
- Rich theoretical tools
- Few computational techniques

・ 同 ト ・ ヨ ト ・ ヨ ト ・

Advantages:

- General valuation distribution
 - beyond e.g., strong monotonicity assumptions about value per click across slots

э

- Most existing literature analyzes position auctions as unrepeated, perfect-information interactions
 - unrepeated: probability one user will click on an ad is independent of the probability for the next user
 - perfect info: bidders can probe each others' values
- Given a valuation model for each advertiser and a fixed number of bid increments, we have a big normal-form game.

向下 イヨト イヨト

- Most existing literature analyzes position auctions as unrepeated, perfect-information interactions
 - unrepeated: probability one user will click on an ad is independent of the probability for the next user
 - perfect info: bidders can probe each others' values
- Given a valuation model for each advertiser and a fixed number of bid increments, we have a big normal-form game.
- Problem: it's a really big normal-form game:
 - e.g., 10 bidders, 8 slots, bids in $\{0, 1, \dots, 40\}$: ~700,000TB

Position Auctions	AGGs	Experimental Setup	Results	Conclusion
Action Graph	Games [Bhat, L-B, 2004; Jiang,	L-B, 2006]	

- A compact representation for perfect-information, simultaneous-move games
 - Like Bayes nets or graphical games: big table \rightarrow directed graph and small tables
 - Nodes correspond to actions. Table gives utility for playing a given action based on number of agents playing each neighboring action.

・日・ ・ ヨ・ ・ ヨ・

Position Auctions	AGGs	Experimental Setup	Results	Conclusion
Action Graph	Games [3hat, L-B, 2004; Jiang	, L-B, 2006]	

- A compact representation for perfect-information, simultaneous-move games
 - $\bullet\,$ Like Bayes nets or graphical games: big table $\rightarrow\,$ directed graph and small tables
 - Nodes correspond to actions. Table gives utility for playing a given action based on number of agents playing each neighboring action.
- Representational savings:
 - Exponentially smaller
 - Even smaller using function nodes (e.g. sum, max)
- Computational savings:
 - Exponential speedup in expected utility calculations
 - Implies exponential speedup in
 - simpdiv [Scarf, 1967];
 - gnm [Govindan, Wilson, 2005]
 - both are implemented in Gambit [McKevley et al, 2006]

Position Auctions	AGGs	Experimental Setup	Results	Conclusion
Specifying de	tails			

- Game size: 10 bidders, 8 slots, values in [0,40]¹
- Game instances: 100 draws from each model
 - assuming a uniform distribution on all free model parameters
 - normalizing the highest value to be equal to the highest bid amount, so that all increments are potentially useful
- Discretization: ties broken randomly, prices rounded up, 1 increment reserve price
- Multiple runs: 10 runs each of simpdiv and gnm, randomized starting points

¹We also considered three other sizes in our paper. $\Box \rightarrow \langle \Box \rangle \rightarrow \langle \Xi \rangle \rightarrow \langle \Xi \rangle$

Computational Analysis of Position Auctions

Position Auctions	AGGs	Experimental Setup	Results	Conclusion
Equilibrium sel	ection			

We need to decide which equilibria to report.

- Why?
 - Our solvers return arbitrary equilibria; many exist.
 - GSP best response set is interval (sets price for bidder above)

・回 ・ ・ ヨ ・ ・ ヨ ・

Position Auctions	AGGs	Experimental Setup	Results	Conclusion
Eauilibrium sel	ection			

We need to decide which equilibria to report.

- Why?
 - Our solvers return arbitrary equilibria; many exist.
 - GSP best response set is interval (sets price for bidder above)
- How?
 - Remove bids above value (always dominated)
 - Thus we restrict to *conservative Nash equilibria* [Paes Leme and Tardos, 2009]
 - Multiple runs
 - SLS through equilibrium space
 - maximize/minimize revenue/welfare

- 4 回 2 - 4 □ 2 - 4 □

Position Auctions	AGGs	Experimental Setup	Results	Conclusion
Statistical me	thods			

- Goal: Quantitative, comparisons across mechanisms
 - $\bullet~$ Is A better than B?
- Problem: Possibly insignificant conclusions.
- Solution: A conservative, nonparametric statistical test, with multiple testing correction.
 - ** denotes significance at or above $p=0.01\,$

Conclusion				

- This approach is possible and yields real economic insights!
- Efficiency: wGSP is more efficient (even in difficult models) and very robust to equilibrium selection.
- Revenue: Ranking is unclear. Equilibrium selection and instance details have large impact.
- Code and data are available at: http://www.cs.ubc.ca/research/position_auctions/

This work was supported by Microsoft's Beyond Search program.

Future work				

- Learning distributions from real-world data
- Generalize representation to other models (e.g. cascade)
- Better game solving techniques (e.g. provable bounds on revenue and welfare)
